deciduous scales. The arrangement and distribution of the scales in itcthyosis are peculiar. Above and below the decranon on the arm, says Dr. Willan, and in similar situation with respect to the petella on the thigh and leg they are small, rounded, prominent, or papillary, and of a black colour; some of the scaly papillæ have a short narrow neck, and broad irregular tops. On some part of the extremilies, and on the trunk of the body, the scales are flat and large often placed like tiling, or in the same order as scales on the back of a fish; but, in a few cases, they have appeared separate, being intersected by whitish furrows. There is usually in this complaint a dryness and roughness of the soles of the feet; sometimes a thickened and brittle state of the skin in the palms of the hands, with large painful fissures, and, on the face, an appearance of the scurf rather than of scales. The inner part of the wrists, the hams, the inside of the elbow, the furrow along the spine, the inner and upper part of the shigh, are perhaps the only portions of the kin always exempt from the scaliness. Patients affected with ichthyosis are occasionally much harassed with inflamed pustules, or with large painful boils on different parts of the body: it is also remarkable, that they never seem to have the least perspiration or moisture of the skin. This disease did not, in any case, appear to Dr. Willan to have been transmitted hereditarily; nor was more than one child from the same parents affected with it. Dr. Willan never met with an instance of the horny rigidity of the integaments, Ichthyosis cornea, impeding the motion of the muscles or joints It is, however, mentioned by authors as affecting the lips, prepuce, toes, fingers, &c. and sometimes as extending over nearly the whole body.

ICTERITIA. (From icterus, the jaundice.) An eruption of yellowish spots. Also a yellow discoloration of the skin, without

ICTERUS. (Named from its likeness to the plumage of the golden thrush, of which Pliny relates, that if a jaundiced person looks on one, the bird dies, and the patient recovers.) Morbus arcuatus, or arquaius. Aurigo. Morbius regius. Morbus lescoli. The jaundice. A genus of disease in the class cachexia, and order im. petigines, of Cullen; characterized by yel. lowness of the skin and eyes; faces white, and urine of a high colour. There are six species :-

3 F \*

1. Icterus calculosus, acute pain in the epigastric region, increasing after eating; gall-stones pass by tools.

2. Icterus spasmodicus, without pain, after spasmodic diseases and passions of the

mind.

3. Icterus mucosus, without either pain, gall-stones, or spasm, and relieved by the discharge of tough phlegm by stool.

4. Icterus hepaticus, from an induration

in the liver.

5. Icterus gravidarum, from pregnancy and disappearing after delivery.

6. Icterus infantum, of infants.

It takes place most usually in consequence of an interrupted excretion of bile, from an obstruction in the ductus communis choledochus, which occasions its absorption into the blood-vessels. In some cases it may, however, be owing to a redundant secretion of the bile.

The causes producing the first of these are, the pressure of biliary calculi in the gall-bladder and its ducts; spasmodic constriction of the ducts themselves; and, lastly, the pressure made by tumours situated in adjacent parts; hence jaundice is often an attendant symptom on a scirrhosity of the liver, pancreas, &c. and frequently like-

wise on pregnancy.

Chronic bilious affections are frequently brought on by drinking freely, but more particularly by spirituous liquors; hence they are often to be observed in the debauchee and the drinker of drams. They are likewise frequently met with in those who lead a sedentary life, and who indulge much in anxious thoughts.

A slight degree of jaundice often proceeds from the redundant secretion of the bile, and a bilious habit is therefore constitutional to some people, but more particularly to those who reside long in a warm

climate.

By attending to the various circumstances and symptoms which present themselves, we shall in general be able to ascertain, with much certainty the real nature of the cause which has given rise to disease.

We may be assured, by the long continuance of the complaint, and by feeling the liver and other parts externally, whether or not it arises from any tumour in this viscus, or the pancreas, mesentery, or

omentum.

Where passions of the mind induce the disease, without any hardness or enlargement of the liver, or adjacent parts, and without any appearance of calculi in the faces, or on dissection after death, we are naturally induced to conclude that the disorder was owing to a spasmodic affection of the biliary ducts.

Where gall-stones are lodged in the fatal, we ducts, acute lancinating pains will be felt sucking.

in the region of the parts, which will cease for a time, and then return again; great irritation at the stomach and frequent vomiting will attend, and the patient will experience an aggravation of the pain after eating. Such calculi are of various sizes, from a pea to that of a walnut; and, in some cases, are voided in a considerable number, being, like the gall, of a yellowish, brownish, or green colour.

The jaundice comes on with langour, inactivity, loathing of food, flatulency, acidities in the stomach and bowels, and costiveness. As it advances in its progress, the skin and eyes become tinged of of a deep yellow; there is a bitter taste in the mouth, with frequent nausea and vomiting; the urine is very high coloured; the stools are of a grey or clayey appearance, and a dull obtuse pain is felt in the right hypochondrium, which is much aggravated by pressure with the fingers:

Where the pain is very acute, the pulse is apt to become hard and full, and other

febrile symptoms to attend.

The disease, when of long continuance, and proceeding from a chronic affection of the liver, or other neighbouring viscera, is often attended with anasarcous swellings,

and sometimes with ascites.

Where jaundice is recent, and is occasioned by concretions obstructing the biliary ducts, it is probable that, by using proper means, we may be able to effect a cure; but where it is brought on by tumours of the neighbouring parts, or has arisen in consequence of other diseases, attended with symptoms of obstructed viscera, our endeavours will most likely not be crowned with success. Arising during a state of pregnancy, it is of little consequence, as it will cease on parturition.

On opening the bodies of those who die of jaundice, the yellow tinge appears to pervade even the most interior part of the body; it is diffused throughout the whole of the cellular membrane, in the cartilages and bones, and even the substancee of the brain is coloured with it. A diseased state of the liver, gall-bladder, or adjacent viscera, is usually to be met with.

The Icterus infantum, or yellow gum, is a species of jaundice, which, for the most part, affects all children at, or soon after, their birth, and which usually continues for

some days.

It has generally been supposed to arise from the meconium impacted in the intestines, preventing the flow of bile into

The effects produced by it are, languor, indolence, a yellow tinge of the skin, and a tendency to sleep, which is sometimes fatal, where the child is prevented from sucking.

leterus albus. The white jaundice, The chlorosis, or green-sickness, is some-

times thus called.

ICTUS. A stroke, or blow. Hence ictus solis means a stroke of the sun, or that affection which takes place from too great an influence of the sun's heat. It signifies also the pulsation of an artery, and the sting of a bee, or other insect.

IDEUS. (From Bn, a mountain in Phrygia, their native place.) A name of the

pæony, and blackberry.

IDIOCRASIA. See Idiosyncrasia.

IDIOPATHIC. (Idiopathicus; from idios, peculiar, and mados, an affection.) A disease which does not depend on any other disease, in which respect it is opposed to a symptomatic disease, which is

dependant on another.

IDIOSYNCRASY. (Idiosyncrasia; from perament.) A peculiarity of constitution, in which a person is affected by certain agents, which, if applied to a hundred other persons, would produce no effect. thus some people cannot see a finger bleed without fainting; and thus violent inflammation is induced on the skin of some persons by substances that are perfectly innocent to others.

IDIOTROPIA. (From Bus, peculiar, and TRETO, to turn.) The same as Idiosyn-

crasia.

IGNATIA AMARA. The systematic name of the plant which affords St. Ignatius's bean. See Faba indica.

IGNATII FABA. See Faba indica. Ignatius's bean. See Faba indica.

IGNIS CALIDUS. A hot fire: so some call a gangrene: also a violent inflammation, just about to degenerate into a gangrene.

IGNIS FRIGIDUS. A cold fire. A sphacelus hath been thus called, because the parts that are so affected become cold as

the surrounding air.

A name of the ery-IGNIS PERSICUS. sipelas, also of the tumour called a car-

Fire for fusion. It is IGNIS ROTE. when a vessel which contains some matter for fusion is surrounded with live, i. e. red hot coals.

IGNIS SACER. A name of erysipelas, and of a species of Herpes.

IGNIS SAPIENTIUM. Heat of horse-dung. IGNIS SILVATICUS. A name of the Im-

petigo. Ignis volagrius. A name of the Impe-

sigo. IGNIS VOLATICUS. See Erysipelas.

IKAN RADIX. A somewhat oval, oblong, compressed root, brought from China. It is extremely rare, and would appear to be the root of the orchis tribe.

ILAPHIS. A name in Myrepsus for the burdock.

ILECH. By this word, Paracelsus seems to mean a first principle.

ILEIDOS. In the Spagyric language it is

the elementary air.

ILEON CRUENTUM Hippocrates describes it in lib De Intern. Affect. In this disease, as well as in the scurvy, the breath it fetid, the gums recede from the teeth, hæmorrhages or the nose happen, and sometimes there are ulcers in the legs, but the patient can move about his business very well.

ILEUM. (From ωλω, to turn about; from its convolusions.) Ileum intestinum. The last portion of the small intestines, about fifteen hands' breadth in length, which terminates at the valve of the ca-

cum. See Intestines.

ILEX. The name of a genus of plants in the Linnaan system. Class, Tetrandria. Order, Tetragynia.

ILEX AQUIFOLIUM. The systematic name of the common holly. See Aquifolium.

ILIA. (The plural of Ile, unn.) The flanks, or that part in which is enclosed the small intestines.

ILIAC ARTERIES. Arteriæ iliacæ. The arteries so called are formed by the bifurcation of the aorta, near the last Inmbar vertebra. They are divided into internal and external. The internal iliac, also called the hypogastric artery, is distributed in the fœtus into six, and in the adult into five branches, which are divided about the pelvis, viz. the little iliac, the gluteal, the ischiatic, the pudical, and the obturatory; and in the fœtus the umbilical. The external iliac proceeds out of the pelvis through Poupart's ligament, to form the femoral artery.

ILIAC PASSION. (EIXEDS, IXEDS, EIXELDS, is described as a kind of nervous colic, whose seat is the ilium.) Passio iliaca. Convolvuius. Volvulus. Miserere mer. Chordapsus. Tormentum. A violent vomiting, in which the facal portion of the food is voided by the mouth.

ILIAC REGION. The side of the hypogastric region, just above the hips.

ILIACUS INTERNUS. Iliacus of Wins-Iliaco trachanten of Dumas. thick, broad, and radiated muscle, which is situated in the pelvis, upon the inner surface of the ilium. It arises fleshy from the inner lip of the ilium, from most of the hollow part, and likewise from the edge of that bone, between its anterior superior spinous process and the acetabulum. It joins with the psoas magnus, where it begins to become tendinous, and passing under the ligamentum Fallopii, is inserted in common with that muscle.

tendon of this muscle has been seen distinct from that of the psoas, and, in some subjects, it has been found divided into two portions. The iliacus internus serves to assist the psoas magnus in bending the tligh, and in bringing it directly forwards.

ILIADUM. Riadus. It is the first matter of all things, consisting of mercury, salt, and sulphur. These are Paracelsus's three principles. His iliadus is also a mineral spirit, which is contained in every element, and is the supposed cause of diseases.

ILIASTER. Paracelsus says it is the occult virtue of nature, whence all things

have their increase.

ILINGOS. (Ιλιγγος: from ιλιγξ, a vortex.) A giddiness, in which all things appear to turn round, and the eyes grow dim.

ILISCUS. Avicennna says it is madness

caused by love.

ILIUM OS. (From ilia, the small intestines: so named because it supports the ilia.) The haunch-bone The superior portion of the os innominatum, which, in the fætus, is a distinct bone. See Innominatum 05.

ILLECEBRA. (From ειλεω, to turn; because its leaves resemble worms.) Vermicularis. Piper murale Sedum minus. Wall pepper. Stone-crop The plant thus called is the Sedum acre of Linnæus; in its recent state it is extremely acrid, like the hydropiper; hence, if taken in large doses, it acts powerfully on the primæ viæ, proving both emetic and cathartic; applied to the skin as a cataplasm, it frequently produces vesications and erosions. Boerhave therefore imagines that its internal employment must be unsafe; but experience has discovered, that a decoction of this plant is not only safe, but of great efficacy in scorbuic complaints. which purpose, a handful of the herb is directed, by Below, to be boiled in eight pints of beer, till they are reduced to four, of which three or four ounces are to be taken every, or every other, morning. Milk has been found to answer this purpose better than beer. Not only ulcers simply scorbutic, but those of a scrophulous, or even cancerous tendency have been cured by the use of this plant; of which Marquet relates several instances. He likewise found it useful as an external application in destroying fungous flesh, and in promoting a discharge in gangrenes and carbuncles. Another effect, for which this plant is esteemed, is that of stopping intermittent fevers.

ILLICIUM. The name of a genus of

plants in the Linnæan system.

ILLICUM ANISATUM. The systematic name of the plant, the seeds of which are called the star aniseed. See Anisum stellatum.

ILLOSIS. (From shaes, the eye.) A distortion of the eyes.

an external medicine, like the Ceroma, with which the limbs of wrestlers, and others delighting in like exercises, were rubbed, especially after bathing; an account of which may be met with in Baccius de Thermis.

ILLUTATIO. (From in, upon, and lutum, mud) Illutation. A besmearing any part of the body with mud, and renewing it as it grows dry, with a view of heating, drying and discussing. It was chiefly done with the mud found at the bottom of mineral springs.

ILLYS. (From ιλλος, the eye.) A person who squints, or with distorted eyes.

ILYS. (From  $\iota \lambda \nu \iota_5$ , mud.) The faces of wine. Also an epithet for sediment in stools which resemble faces of wine; also the sediment in urine, when it resembles the same.

IMBECILLITAS OCULORUM. Celsus speaks

of the Nyctalopia by this name.

IMBIBUTIO. (From imbibo, to receive into.) In chymistry it is a kind of cohobation, when the liquor ascends and descends upon a solid substance, till it is fix e therewith.

Immersus. A term given by Bartholine, and some other anatomists, to the Subscapularis muscle, because it was hidden, or, as it were sunk.

IMPATIENS. (From in, not, and putior, to suffer; because its leaves recede from the hand with a crackling noise, as impatient of the touch.) A species of persicaria.

IMPERATORIA. (From impero, to overcome; so named because, its leaves exend and overwhelm the lesser herbs which grow near it.) 1. The name of a genus of plants in the Linnæan system. Class, Pentandria. Order, Monogynia.

2. The pharmacopoial name of the Imperatoria ostruthium of Linnæus. Magistrantia. Master-wort. The roots of this plant are imported from the Alps and Pyrences, notwithstanding it is indigenous to this island: they have a fragrant smell, and a bitterish pungent taste. The plant, as its name imports, was formerly thought to be of singular efficacy; and its great success, it is said, caused it to be distinguished by the name of divinum remedium. At present it is considered merely as an aromatic, and consequently is superseded by many of that class which possess superior quadities.

IMPERATORIA OSTRUTHIUM. The systematic name of the master-wort. See

Imperatoria

impertion impeto, to infest.) An order in the class cachexia of Cullen, the genera of

which are characterized by cachexia, deforming the external parts of the body with

tumours, eruptions, &c.

IMPETIGO. This affection, as described by authors, is a disease in which several red, hard, dry, prurient spots arise in the face and neck, and sometimes all over the body, and disappear by furfuraceous or t nder scales.

IMPIA HERBA. (From in, not, and pius, good; because it grows only on barren ground.) A name given to cudweed.

IMPLICATED. Celsus, Scribonius, and some others, call those parts of physic so, which have a necessary dependence on one another: but the term has been more significantly applied, by Bellini, to such fevers, where two at a time afflict a person, either of the same kind, as a double tertian; or of different kinds, as an intermittent tertian, and a quotidian, called a Semitertian.

IMPLUVIUM. (From impluo, o hower The shower-bath. An embro-

cation.

IMPREGNATION. See Conception and Generation.

INANITIO. (From inanio, to empty.) Inanition. Applied to the body, it means evacuation; applied to the mind, it means a defect of its powers

INCANTATION. Incantatio. Incantamen-A way of curi g diseases by charms, defended by Paracelsus, Helmont, and some other chymical enthusiasts.

INCENDIUM. (From incendo, to burn.) A burning fever, or sometimes any burning heat.

INCENSIO. The same as Incendium.

Also a hot inflammatory tumour.

INCERNICULUM. (From incerno, to sift.) A strainer, or sieve. In anatomy, it is a name for the polvis of the kidney, from its office as a strainer.

INCIDE. (From incido, to cut.) Medicines were formerly so called which consist of pointed and sharp particles, as acids, and most salts, which are said to incide or cut the phlegm, when they break it so as to occasion its discharge.

INCIDENTIA. (From incido, to cut.) Al-Medicines supposed to cut viscid terantia.

humours.

INCINERATIO. (From incinero, to reduce to ashes.) Incineration. The reducing of any thing to ashes by fire.

Incisivus inferior. Sce Levator labii

inferioris.

Incisivus LATERALIS. See Levator labii superioris alaque nasi. See Depressor labii

Incisivus Medius. superioris alæque nasi.

INCISORIUM. (From incido, to cut.) table whereon a patient is laid for an ope-

INCISORIUM FORAMEN. A name of the foramen, which lies behind the dentes incisores of the upper jaw.

INCISORS. (Dentes incisores; from incido, to cut, from their use in cutting the The four front teeth of both jaws are so called, because they cut the food. See Teeth.

INCONTINENTIA. (From in and contineo, to contain ) Inability to retain the natural evacuations.

INCRASSANTIA. (From incrasso, to make thick.) Medicines thickening the .

fluids. INCUBUS. (From incubo, to lie upon; because the patient fancies that something

lies upon his chest.) See Night-mare, and Oneirodynia

INCUS. (A smith's anvil, from incudo, to smite upon; so named from its likeness in shape to an anvil.) The largest and strongest of the bones of the ear in the tympanein. It is divided into a body and two crura. Its body is situated anteriorly, is rather broad and thick, and has two eminences and two depressions, both covered with cartilage, and intended for the recept on of the head of the malleus. Its shorter crus extends no farther than the cells of the mastoid apophysis. Its longer crus, together with the mainibrium of the malleus, to which it is connected by a ligament, is of the same extent as the shorter, but its extremity is curved inwards, to receive the os orbiculare, by the intervention of which it s united with the stapes.

INDEX (From indico, to point out; because it is generally used for such purposes.) The fore-finger.

Indian arrow-root. See Maranta.

Indian cress. See Nasturtium indicum. INDIAN DATE-PLUM. The fruit of the Diospyrus lotus of Linnaus. When ripe it has an agreeable taste, and is very nutritious.

Indian leaf. See Cassia lignea. Indian pink. See Spigelia.

INDIAN RUBBER. The substance known by the names Indian rubber, Elasiic gum, Cayenne resin, Cautchuc, and by the French Caoutchouc, is prepared from the juice of the Siphonia elastica; -foliis ternatis elleptisis integerrimis subtus canis longe peliolatis. Suppl. plant. The man ner of obtaining this juice is by making incisions through the bark of the lower part of the trunk of the tree, from which the fluid resin issues in great abundance, appearing of a milky whiteness as it flows into the vessel placed to receive it, and into which it is conducted by means of a tube or leaf fixed in the incision, and supported with clay. On exposure to the air, this milky juice gradually inspissates into a soft, reddish, elastic resin. It is formed by the Indians in South America into various figures, but is commonly brought to Europe in that of speer-shaped bottles, which are said to be formed by spreading

the juice of the Siphonia over a proper mould of clay; as soon as one layer is dry. another is added, until the bottle be of the thickness desired. It is then exposed to a thick dense smoke, or to a fire, until it becomes so dry as not to stick to the fingers, when, by means of certain instruments of iron, or wood, it is ornamented on the outside w th various figures. This being done, it remains only to pick out the mould, which is easily effected by softening it with water. Indian rubber may be subjected to the action of some of the most powerful menstrua, without suffering the least change, while its pliability and elasticity are eminently peculiar to itself. Its proper menstruum is known to some persons in England, who keep it a profound sccret, and prepare the gum into beautiful catheters, bougies, syringes, pessaries, &c.

Indian wheat. See Zea mays.
Indiana Radix. Ipeca uanha.
Indica camores. Potatoes.

INDICANS. Indicant. The proximate cause of a disease, or that from which the indication is drawn.

INDICATING DAYS, are the same as criti-

cal days.

INDICATION (Indicatio; from indico, to shew.) An indication is that which demon trates in a disease what ought to be donc. It is three-fold: preservation, which preserves health; curative, which expels a present disease; and vital, which respects the powers and reasons of dict. The scope from which indications are taken, or determined, is comprehended in this distich;

—— Ars, ætas, regio, camplexio, virtus,
Mos et symptoma, repletio, tempus et

INDICATOR. (From indico, to point; so named from its office of extending the index, or fore-finger.) Extensor indicis of Cowper. Extensor secundi internodii indicis, proprius vulgo indicator of Douglas, and Cubito-sus phalangettien de l'indix of Dumas. An extensor muscle of the forefinger, situated chiefly on the lower and posterior part of the fore-arm. It arises, by an acute fleshy beginning, from the middle of the posterior part of the ulna; its tendon passes under the same ligament with the extensor digitorum communis, with part of which it is inserted into the posterior part of the fore-finger.

Indicum Lignum. Logwood.
Indicus. Sweet and bitter costus.

Indicus morbus. The venereal disease.

INDIGENOUS. (Indigenus; from indu, within, and gigno, to beget.) Applied to diseases which are local, or peculiar to any coun'ry.

INDURANTIA. (From induro, to harden.)

Medicines which harden.

INDUSIUM. (From induo, to put on.)

A shirt. Also the name of the amnior, from its covering the fœtus like a shirt.

Inesis. (From man, to evacuate.) Inchus. An evacuation of the humours.

INFECTION. See Contagion.

INFERNAL. A name given to a caustic, lapis infernalis, from its strong burning property.

INFIBULATIO. (From infibulo, to button together.) An impediment to the retraction

of the prepuce.

INFLAMMABLE. Chymists distinguish by this term such bodies of the mineral kingdom only as burn with facility, and flame in an increased temperature.

INFLAMMATION. (Inflammatio; from inflammo, to burn.) Phlogosis. Phlegmasia, A genus of discase in the class pyrexia, and order phlegmasia, of Cullen.

This disease is characterized by heat, pain, redness, attended with more or less of tumefaction and fever. Inflammation is divided into two species, viz. phlegmonous and erysipelatous.

Besides this division, inflammation is either acute or chronic, local or general, simple, or complicated with diseases.

Phlegmonous inflammation is known by its bright red colour, tension, heat, and a circumscribed, throbbing, painful tume faction of the part, tending to suppuration. Phlegmon is generally used to denote an inflammatory tumour, situated in the skin, or cellular membrane. When the same disease affects the viscera, it is usually called phlegmonous inflammation.

Erysipelatous inflammation is considered as an inflammation of a dull red colour, vanishing upon pressure, spreading unequally, with a burning pain and tumour scarcely perceptible, ending in vesicles, or desquamation. This species of inflammation admits of a division into erythema, when there is merely an affection of the skin alone, with very little of the whole system, and erysipelas, when there is general affection of the system.

The fever attending erysipelatous inflanmation is generally synochus, or typhus, excepting when it affects very vigorous habits, and then it may be synocha.

The fever attending phlegmonous inflammation is almost always synocha. Persons in the prime of life, and in full vigour, with a plethoric habit of body, are most hable to the attacks of phlegmonous inflammation; whereas those advanced in years, and those of a weak habit of body, irritable, and lean, are most apt to be attacked with erysipelatous inflammation.

Phlegmonous inflammation terminates in resolution, suppuration, gangrene, and

scirrhus, or induration.

Resolution is known to be about to take place when the symptoms gradually abates suppuration, when the inflammation does not readily yield to proper remedies; the

throbbing increases, the tumour points and is external, and rigors come on. Gangrene is about to take place when the pain abates, the pulse sinks, and cold perspirations come on. Scirrhus, or inducation, is known by the inflanmation continuing a longer time than usual; the tuniefaction continues, and a considerable hardness remains. This kind of tumour gives little or no pain, and, when it takes place, it is usually the sequel of inflammation, affecting glandular parts. It sometimes, however, is accompanied with lancinating pains, ulcerates, and becomes cancerous.

Erythematous inflammation terminates in resolution, suppuration, or gangrene. The symptoms of inflanimation are account-

ed for in the following way.

The redness arises from the dilatation of the small vessels, which become sufficiently large to admit the red globules in large quantities; it appears also to occur, in some case, from the generation of new vessels. The swelling is caused by the dilatation of the vessels, the phlethoric state of the arteries and veins, the exudation of coagulable lymph into the intestices of the cellular membrane, and the interruption of absorption.

In regard to the augmentation of heat, as the thermometer denotes, very little increase of temperature; it appears to be accounted for from the increased sensibility of the nerves, which convey false impressions to the sensorium. The pain is occasioned by a deviation from the natural state of the parts, and the unusual condition into which the nerves are thrown, The throbbing depends on the increased

action of the arteries.

Blood taken from a person labouring under active inflammation, exhibits a yellowish white crust on the surface; this is denominated the buffy coriaceous, or inflammatory coat. This consists of a layer of coagulable lymph, almost destitute of red globules. Blood, in this state, is often termed sizy. The colouring part of the blood is its heaviest constituent: and, as the blood of a person labouring under in-flammation is longer coagulating than healthy blood, it is supposed that the red globules have an opportunity to descend to a considerable depth from the surface before they become entangled. The buffy coat of blood is generally the best criterion of inflammation; there are a few anomalous constitutions in which this state of blood is always found, but these are rare.

The occasional and exciting causes of imflammation are very numerous; they, however, may generally be classed under external violence, produced either by mechanical or chemical irritation, changes of temperature and stimulating foods. Fever often seems to be a remote cause; the inflammation thus produced is generally considered as critical. Spontaneous inflam-

mation sometimes occurs when no perceptible cause can be assigned for its production. Scrofula and syphillis may be considered as exciting causes of inflammation.

With regard to the proximate cause, it has been the subject of much dispute. Galen considered phlegmon to be produced by a superabundance of the humor sanguineus. Boerhaave referred the proximate cause to an obstruction in the small vessels, occasioned by a viscosity or lenton of the blood. Cullen and others attributed it rather to an affection of the vessels than a change of the fluids.

The proximate cause, at the present period, is generally considered to be a mor-bid dilatation, and increased action of such arteries as lead and are distributed to the

inflamed part.

Inflammation of the brain. See Phrenitis, Inflammation of the bladder. See Cys-

Inflammation of the eyes. See Ophthalmia. Inflammation of the intestines. See En-

Inflammation of the kidneys. See Ne-

Inflammation of the liver. See Hepatitis. Inflammation of the lungs. See Perip-

Inflammation of the peritoneum.

Inflammation of the plenra. See Pleuritis. Inflammation of the stomach, See Gas-

Inflammation of the uterus. See Hyste-

INFLATIO. (From inflo, to puff up.) A windy tumour, or swelling. See Em-

INFLATIVA. (From inflo, to puff up with wind.) Medicines, or food, which cause flatulence.

INFLUENZA. (The Italian word for influence. The disease is so named because it was supposed to be produced by a peculiar influence of the stars.) See Catarrhus à contagione.

INFRASCAPULARIS. (From infra, beneath, and scapula, the shoulder-blade.) A muscle named from its position beneath

the scapula.

INFRASPINATUS. (From infra, be-

nea h, and spina, the spine )

INFUNDIBULUM (From infundo, to pour in.) 1. A canal that proceeds from the vulva of the brain to the pituitary gland in the sella turcica.

2. The beginnings of the excretory duct of the kidney, or cavities into which the urine is first received, are called infundibula.

INFUSION. (Infusum; from infundo, to pour in.) Infusio. A process that consists in pouring water of any required degree of temperature on such substances as

have a loose texture, as thin bark, wood in shavings, or small pieces, leaves, flowers, &c. and suffering it to stand a certain time. The liquor obtained by the above process is called an infusion. The following are among the most approved infusions.

INFUSUM ANTHEMIDIS. Infusion of chamomile. " Take of chamomile flowers, half an ounce; boining water, a pint" Macerate for ten minutes, in a covered vessel, and strain. For its virtues see Chamemelum.

INFUSUM ARMORACIÆ COMPOSITUM. Compound infusion of horse-radish. "Take of fresh horse-radish-root, sliced, mustardseeds bruised, of each one ounce; boiling water, a pint." Macerate for two hours, in a covered vessel, and strain; then add compound spirit of horse-radish, a fluid ounce. See Ruphanus rusticanus.

INFUSUM AURANTII COMPOSITUM. Compound infusion of orange-peel. "Take of orange peel, dried, two drachms; lemonpeel, fresh, a drachm; cloves, bruised, half a drachm; boiling water, half a pint."
Macerate for a quarter of an hour, in a covered vessel, and strain. See Auran-

INFUSUM CALUMBE. Infusion of calumba. "Take of calumba-root, sliced, a drachm; boiling water, half a pint." Macerate for two hours, in a covered vessel, and strain. See Columba.

INFUSUM CARYOPHYLLORUM. Infusion of cloves. "Take of cloves, bruised, a drachm and a half; boiling water, half a pint." Macerate for two hours, in a covered vessel, and strain. See Caryophyllum.

INFUSUM CASCARILLE. Infusion of cascarilla. " Take of cascarilla-bark, bruised, half an ounce; boiling water, half a pint."
Macerate for two hours, in a covered vessel, and strain. See Cascarilla.

INFUSUM CATECHU. Infusion of catechu. " Take of extract of catechu, two drachms and a half; cinnamon bark, bruised, half a drachm; boiling water, half a pint." Macerate for an hour, in a covered vessel, and strain. See Catechu.

INFUSUM CINCHONA. Infusion of cinchona. "Take of lance-leaved cincliona bark, half an ounce; boiling water, half a pint." Macerate for two hours, in a covered vessel, and strain. See Cinchona.

INFUSUM CUSPARIE. Infusion of cusparia. "Take of cusparia bark, bruised, two drachms; boiling water, half a pint." Macerate for two hours, in a covered vessel, and strain. See Augustura.

INFUSUM DIGITALIS. Infusion of foxglove. "Take of purple fox-glove leaves, dried and powdered, a drachm; boiling water, half a drachm." Macerate for two hours, in a covered vessel, and strain; then add spirit of cinnamon, half a fluid ounce. See Digitalis.

INFUSUM GENTIANÆ COMPOSITUM. Compound infusion of gentian. "Take of gentian-root, sliced, orange-peel, dried, of each a drachm; lemon-peel, fresh, two drachms; boiling water, twelve ounces."
Macerate for an horr, in a covered vessel, and strain. See Gentiana.

Infusion of linseed. INFUSUM LINI. "Take of linseed, an ounce; liquorice-root, sliced, half an ounce; boiling water, two pints." Macerate for two hours, near the fire, in a covered vessel, and strain. See Linum.

INFUSUM QUASSIÆ, Infusion of quassia. " Take of quassia wood, a scruple; boiling water, half a pint." Maccrate for two hours, and strain. See Quassia.

INFUSUM RHÆ1. Infusion of rhubarb. "T ke of rhubarb root, sliced, a drachm; boiling water, half a pint." Macerate for two hours, and strain. See Rhab irbarum.

INFUSUM ROSE. "Take of the petals of red rose, dried, half an ounce; boiling water, two pints and a half; delute sulphuric acid, three fluid drachms; double-refined sugar, an ounce and a half." Pour the water upon the petals of the rose in a covered glass vessel; then add the acid, and macerate for half an hour. Lastly, strain the infusion and add the sugar to it,

INFUSUM SENNÆ. Infusion of senna. "Take of senna-leaves, an ounce and half; ginger-root, sliced, a drachm; boiling water, a pint." Macerate for an hour, in a covered vessel, and strain the liquor.

INFUSUM SIMAROUBE. Infusion of simarouba. "Take of simarouba-bark, bruised, half a drachm; boiling water, half a pint." Macerate for two hours, in a covered vessel, and strain. See Simarouba.

INFUSUM TABACI. Infusion of tobacco. "Take of tobacco-leaves, a drachm; boiling water, a pint" Macerate for an hour, in a covered vessel, and strain. See Nicotiana. INGLUVIES. The claw, crop, or gorge of

a bird. Also gluttony.

INGRAVIDATION. (From ingravidor, to be great with child.) The same as impregnation, or going with child.

INGUEN. The groin. The lower and lateral part of the abdomen, above the thigh

Inguinal ligament. See Poupart's liga-

Inguinal hernia. See Hernia.

INHUMATION. (From inhumo, to put into the ground.) The burying a patient in warm or medicated earth. Some chymists have tancied thus to call that kind of diges. tion, which is performed by burying the materials in dung, or in the earth.

INION. (From 15, a nerve; as being the place where nerves originate.) The occiput. Blancard says it is the beginning of the spinal marrow: others say it is the back part of the neck.

INJACULATIO. (From injaculor, to shoot into.) So Helmont calls a disorder largest of the two. The ends of this spine which consists of a violent spasmodic pain in the stomach, and an immobility of the body.

INJECTION. (From injicio, to cast into.) A medicated liquor, to throw into a natural or preternatural cavity of the body by means of a syringe.

INNOMINATA ARTERIA. The first branch given off by the arch of the aorta. It soon divides into the right carotid and

right subclavian arteries.

INNOMINATUM OS. (Innominatus; from in, priv. and nomen, a name; so called because the three bones of which it originally was formed grew together, and formed one complete bone, which was then left nameless.) A large irregular bone, situated at the side of the pelvis. It is divided into three portions, viz. the iliac, ischiatic, and pubic, which are usually described as three distinct bones.

The os ilium, or haunch bone, is of a very irregular shape. The lower part of it is thick and narrow; its superior portion is broad and thin, terminating in a ridge, called the spine of the ilium, and more commonly known by the name of the haunch. This spine rises up like an arch, being turned somewhat outward, and from this appearance, the upper part of the pelvis, when viewed together, has not been improperly compared to the wings of a phacton. This spine, in the recent subject, appears as if tipped with cartilage; but this appearance is nothing more than the tendinous fibres of the muscles that are inserted into it. Externally, this bone is unequally prominent, and hollowed for the attachment of muscles; and internally, at its broadest fore-part, it is smooth and concave. At its lower part, there is a considerable ridge on its inner surface. This ridge, which extends from the os sacrum, and corresponds with a similar prominence, both on that bone and the ischium, forms, with the inner part of the ossa pubis, what is called the brim of the pelvis. The whele of the internal surface, behind this ridge, is very unequal. The os ilium has likewise a smaller surface posteriorly, by which it is articulated to the sides of the os sacrum. This surface has, by some, been compared to the human ear, and by others, to the head of a bird; but neither of these comparisons seem to convey any just idea of its form or appearance. Its upper part is rough and porous; lower down it is more solid. It is firmly united to the os sacrum by a cartilaginous sub-stance, and likewise by very strong l.gamentous fibres, which are extended to that bone from the whole circumference of this irregular surface. The spine of this bone, which is originally an epiphysis, has two considerable tuberosities, one anteriorly, and the other posteriorly, which is the

too, from their projecting more than the parts of the bone below them, are called spinal processes. Before the anterior spinal process the spine is hollowed, where part of the Sartorius muscle is placed; and below the posterior spinal process there is a very large niche in the bone, which, in the recent subject, has a strong ligament stretched over its lower part, from the os sacrum to the sharp-pointed process of the ischium; so that a great hole is formed, through which pass the great sciatic nerve and the posterior crural vessels under the pyriform mu-cle, part of which is likewise lodged in this hole. The lowest, thickest, and narrowest part of the ilium, in conjunction with the other two portions of each os innominatum, helps to form the acetabulum for the os femoris.

The os ischium, or hip bone, which is the lowest part of the three portions of each os innominatum, is of a very irregular figure, and usually divided into its body, tuberosity, and ramus. The body, externally, forms the inferior portion of the acetabulum, and sends a sharp-pointed process backwards, called the spine of the ischium, This is the process to which the ligament is attached, which was just now described as forming a great foramen for the passage of the sciatic nerve. The tuberosity is large and irregular, and is placed at the inferior part of the bone, giving origin to several muscles. In the recent subject it seems covered with a cartilaginous crust; but this appearance, as in the spine of the ilium, is nothing more than the tendinous fibres of the muscles that are inserted into it. This tuberosity, which is the lowest portion of the trunk, supports us when we sit. Between the spine and the tuberosity is observed a sinuosity, covered with a cartilaginous crust, which serves as a pulley, on which the obturator muscle plays. From the tuberosity, the bone, becoming narrower and thinner, forms the ramus, or branch, which, passing forwards and up-wards, makes, with the ramus of the os pubis, a large hole of an oval shape, the foramen magnum ischii, which affords, through its whole circumference, attachment to muscles. This foramen is more particularly noticed in describing the os pubis.

The os pubis, or share-bone, which is the smallest of the three portions of the os innominatum, is placed at the upper and fore part of the pelvis, where the two ossa pubis meet, and are united to each other by means of a very strong cartilage, which constitutes what is called the symphysis pubis. Each os pubis may be divided into its body, angle, and ramus. The body, which is the outer part, is joined to the os ilium. The angle comes forward to form the symphysis, and the ramus is a thin

apophysis, which, uniting with the ramus of the ischium, forms the foramen magnum ischii, or thyroideum, as it has been sometimes called, from its resemblance to a door, or shield. This foramen is somewhat wider above than below, and its greatest diameter is, from above downwards, and obliquely from within outwards. In the recent subject it is almost completely closed by a strong fibrous membrane, called the obdurator ligament. Upwards and outwards, where we observe a niche in the bone, the fibres of this ligament are separated, to allow a passage to the posterior crural nerve, an artery, and vein. The great uses of this foramen seem to be to lighten the bones of the pelvis, and to afford a convenient lodgment to the obturator muscles. The three bones now described as constituting the os innominatum on each side, all concur to form the great acetabulum, or cotyloid cavity, which receives the head of the thigh-bone; the os ilium and os ischium making each about two-fifths, and the os pubis one-fifth of the cavity. This acetabulum, which is of considerable depth, is of a spherical shape. Its brims are high, and, in the recent subject, is tipped with cartilage. These brims, however, are higher above and externally than they are internally and below, where we observe a niche in the bone (which is the ischium), across which is stretched a ligament, forming a hole for the transmission of blood-vessels and nerves to the cavity of the joint. The cartilage, which lines the acetabulum, is thickest at its circumference, and thinner within, where a little hole is to be observed, in which are placed the apparatus that serves to lubricate the joint, and facilitate its motions. We are likewise able to discover the impression made by the internal ligament of the os femoris, which, by being attached both to this cavity and to the head of the os femoris, helps to secure the latter in the acetabulum. The bones of the pelvis serve to support the spine and upper parts of the body, to lodge the intestines, urinary bladder, and other viscera; and likewise to unite the trunk to the lower extremities. But besides these uses, they are destined, in the female subject, for other important purposes; and the accoucheur finds, in the study of these bones, the foundation of all midwifery knowledge. Several eminent writers are of opinion that in difficult parturition, all the bones of the pelvis undergo a certain degree of separation. It has been observed likewise, that the cartilage uniting the ossa pubis is thicker, and of a more spongy texture, in women than in men, and therefore more likely to swell and enlarge during pregnancy. That many instances of a partial separation of these bones, during labour, have happened, there can be no

doubt; such a separation, however, ought by no means to be considered as an uniform and salutary work of nature, as some writers seem to think, but as the effect of disease. But there is another circumstance, in regard to this part of Osteology, which is well worthy of attention; and this is, the different capacities of the pelvis in the male and female subject. It has already been observed, that the os sacrum is shorter and broader in women than in men; the ossa ilia are also found more expanded; whence it happens, that in women the centre of gravity does not fall so directly on the upper part of the thigh as in men, and this seems to be the reason why, in general, they step with less firmness, and move their hips forwards in walking. From these circumstances also, the brim of the female pelvis is nearly of an oval shape, being considerably wider from side to side, than from the symphysis pubis to the os sacrum; whereas, in man it is rounder, and every where of less diameter The inferior opening of the pelvis is likewise proportionably larger in the female subject, the ossa ischia being more separated from each other, and the foramen ischii larger, so that, where the os ischium and os pubis are united together, they form a greater circle; the os sacrum is also more hollowed, though shorter, and the os coccygis more loosely connected, and therefore capable of a greater degree of motion than in men.

INNOMINATI NERVI. A name of the fifth

pair of nerves.

INOCULATION. The insertion of a poison into any part of the body. It is mostly practised with that of the small-pox, because we have learnt, from experience, that by so doing we shall generally procure fewer pustules, and a much milder disease, than when the small-pox is taken in a natural way. Although the advantages are evident, yet objections have been raised against inoculation, on the notion that it exposes the person to some risk, when he might have passed through life without ever taking the disease naturally; but it is well known that he will be exposed to much greater danger, from the intercourse which he must have with his fellowcreatures, by taking the disorder in a natural way. It has also been adduced, that a person is liable to take the small-pox a second time, when produced at first by artificial means; but such instances are very rare, besides not being sufficiently authentic. We may conjecture that, in most of those cases, the matter used was not variolous, but that of some other eruptive disorder, such as the chicken-pox, which has often been mistaken for the small pox.

To illustrate the benefits arising from inoculation, it has been calculated that a third of the adults die who take the disease

in a natural way, and about one-seventh of the children; whereas, of those who are inoculated, and are properly treated afterwards, the proportion is probably not greater than one in five or six hundred.

Inoculation is generally thought to have been introduced into Britain from Turkey, by Lady Mary Wortley Montague, about the year 1721, whose son had been inuoculated at Constantinople, during her residence there, and whose infant daughter was the first that underwent the operation in this country. It appears to have been well known before this period, both in the South of Wales and Highlands of Scotland. Mr. Mungo Park, in his travels into the interior of Africa, found that inoculation had been long practised by the negroes on the Guinea coast; and nearly in the same manner, and at the same time of life, as in Europe.

It is not clearly ascertained where inoculation really originated. It has been ascribed to the Circassians, who employed it as a mean to preserve the beauty of their women. It appears more probable that accident first suggested the expedient among the different nations, to whom the small-pox had long been known, independent of any intercourse with each other; and what adds to the probability of this conjecture is, that in most places where inoculation can be traced back, for a considerable length of time, it seems to have been practised chiefly by old women, before it was adopted by regular meetitioners.

ed by regular practitioners.

Many physicians held inoc

Many physicians held inoculation in the greatest contempt at first, from its supposed origin; others again discredited the fact, while others, on the testimony of the success in distant countries, believed in the advantages it afforded, but still did not think themselves warranted to recommend it to the families they attended; and it was not until the experiment of it had been made on six criminals (all of whom recovered from the disease, and regained their liberty,) that it was practised, in the year 1726, on the royal family, and afterwards adopted as a general thing.

To insure success from inoculation, the following precautions should strictly be at-

tended to,

1. That the person should be of a good habit of body, and free from any disease, apparent or latent, in order that he may not have the disease and a bad constitution, or perhaps another disorder, to struggle with at the same time.

2. To enjoin a temperate diet and proper regimen; and, where the body is plethoric, or gross, to make use of gentle purges, together with mercurial and antimonial

medicines.

3 That the age of the person be as little advanced as possible, but not younger, if it can be avoided, than four months.

4. To choose a cool season of the year, and to avoid external heat, either by exposure to the sun, sitting by fires, or inwarm chambers, or by going too warmly clothed, or being too much in bed.

5. To take the matter from a young subject, who has the small pox in a favourable way, and who is otherwise healthy, and free from disease; and, when fresh matter can be procured, to give it the preference.

Where matter of a benign kind cannot be procured, and the patient is evidently in danger of the casual small-pox, we should not, however, hesitate a moment to inoculate from any kind of matter that can be procured, as what has been taken in malignant kinds of small-pox has been found to produce a very mild disease.

The mildness or malignity of the d sease appears, therefore, to depend little at all on the inoculating matter. Variolous matter, as well as the vaccine, by being kept for a length of time, particularly in a warm place, is apt, however, to und rgo decomposition, by purrefaction; and then another kind of contagious material has

been produced.

In inoculating, the operator is to make the slightest puncture or scratch imaginable in the arm of the person, rubbing that part of the lancet which is besmeared with matter repeatedly over it, by way of insuring the absorption; and in order to prevent its being wiped off; the shirt sleeve ought not to be pulled down until the part

is perfectly dry.

A singular circumstance attending inoculation is, that when this fails in producing the disease, the inoculated part nevertheless sometimes inflames and suppurates, as in cases where the complaint is about to follow; and the matter produced in those cases is as fit for inoculation as that taken from a person actually labouring under the disease. The same happens very frequently in inoculation for the cow-pox.

If, on the fourth or fifth day after the operation, no reduess, or inflammation, is apparent on the edge of the wound, we ought then to inoculate in the other arm, in the same manner as before; or, for greater certainty, we may do it in both.

Some constitutions are meapable of having the disease in any form. Others do not receive the disease at one time, however freely exposed to its contagion, even though repeatedly insculated, and yet receive it afterwards by merely approaching those labouring under it.

On the coming on of the febrile symptoms, which is generally on the seventh day in the inoculated small pox, the patient is not to be suffered to lie a bed, but should be kept cool, and partake freely of antiseptic cooling drinks.

INOSCULATION. (From in, and osculum, a little mouth.) The running of

the veins and arteries into one another, or the interunion of the extremities of arteries

and veins.

INSANIA. (From in, not, and sanus, sound.) Insanity, or deranged imagination. A genus of disease in the class neuroses, and order vesania, characterized by erroneous judgment, from imaginary perceptions, or recollections, attended with agreeable emotions in persons of a sangume temperament. See Mania.

Insessus. (From insideo, to sit upon.) A vapour-bath, over which the patient sits. Instity.ns. (From insidior, to deceive.) A name for diseases which betray no previous symptoms, but are ready to break out

by surprise.

INSIPIENTIA. (From in, and sapientia, wisdom.) A low degree of delirium, with-

out fever.

INSOLATIO. (From in, upon, and sol, the sun.) A disease which arises from a too great influence of the sun's heat upon the head

INSPIRATION. (From in, and spiro, to breathe.) The act of drawing the air into

the lungs. See Respiration.

INTERCOSTAL ARFERIES. Arteriæ intercostales. The arteries which run between the ribs. The superior intercostal artery is a branch of the subclavian. The other intercostal arteries are given off from the aorta.

INTERCOSTAL MUSCLES. Intercostales externi et interni. Between the ribs, on each side, are eleven double rows of muscles. These are the intercostales externi and interni. Galen has very properly observed, that they decussate each other like the strokes of the letter X. The intercostales externi arise from the lower edge of each superior rib, and, running obliquely downwards and forwards, are inserted into the upper edge of each inferior rib, so as to occupy the intervals of the ribs, from as far back as the spine to their cartilage; but from their cartilages to the sternum, there is only a thin aponeurosis covering the internal intercostales. The intercostales interni arise and are inserted in the same manner as the external. They begin at the sternum, and extend as far as the angles of the ribs, their fibres running obliquely backwards. These fibres are spread over a considerable part of the inner surface of the ribs, so as to be longer than those of the external intercostals. Some of the posterior portions of the internal intercostals pass over one rib, and are inscrted into the rib below. Verheyen first described these portions as separate muscles, under the name of infra costales. Winslow has adopted the same name. Cowper, and after him Douglas, calls them costarum depressores proprii. These distinctions, however,

are altogether superfluous, as they are evi-

dently nothing more than appendages of

the intercostals. The number of these portions varies in different subjects. Most commonly there is only four, the first of which runs from the second rib to the fourth, the second from the third rib to the fifth, the third from the fourth rib to the sixth, and the fourth from the fifth rib to The internal intercostals of the seventh. the two inferior false ribs are frequently so thin, as to be with difficulty separated from the external; and, in some subjects, one or both of them seem to be altogether wanting. It was the opinion of the ancients, that the external intercostals serve to elevate, and the internal to depress the ribs. They were probably led to this opinion, by observing the different direction of their fibres; but it is now well known, that both have the same use, which is that of raising the ribs equally during inspiration. Fallopius was one of the first who ventured to call in question the opinion of Galen on this subject, by contending that both layers of the intercostals serve to elevate the ribs. In this opinion he was followed by Hieroymus Fabricius, our countryman Mayow and Borelli. But, towards the close of the last century, Bayle, a writer of some eminence, and professor at Toulouse, revived the opinon of the ancients by the following arguments. He observed, that the oblique direction of the fibres of the internal intercostals is such, that, in each inferior rib, these fibres are nearer to the vertebræ than they are at their superior extremities, or in the rib immediately above; and that, of course, they must serve to draw the rib downwards, as towards the most fixed point. This plausible doctrine was ad pted by several eminent writers, and, amongst others, by Nicholls, Hoadley, and Shreiber; but, above all, by Hamberger, who went so far as to assert, that not only the ribs, but even the sternum, are pulled downwards by these muscles, and constructed a particular instrument to illustrate this doctrine. He pretended, likewise, that the intervals of the ribs are increased by their elevation, and diminished by their depression; but he allowed that, while those parts of the internal intercostals that are placed between the bony part of the ribs pull them downwards, the anterior portions of the muscle, which are situated between the cartilages, concur with the external intercostals in raising them upwards. These opinions gave rise to a warm and interesting controversy, in which Hamberger and Haller were the principal disputants. The former argued chiefly from theory, and the latter from experiments on living animals, which demonstrate the fallacy of Hamberger's arguments, and prove, beyond a doubt, that the internal intercostals perform the same functions as the external.

INTERCOSTAL NERVE. Acrous in-

tercostalis. Great intercostal nerve. Sym- of the hand .- The interossei interni are pathetic nerve. The great intercostal nerve arises in the cavity of the cranium, from a branch of the sixth and one of the fifth pair, uniting into one trunk, which passes out of the cranium through the carotid canal, and descends by the sides of the bodies of the vertebræ of the neck, thorax, loins, and os sacrum: in its course it receives the small accessory branches from all the thirty pair of spinal nerves. In the neck, it gives off three cervical ganglions, the upper, middle, and lower; from which the cardiac and pulmonary nerves arise. In the thorax, it gives off the splanclinic or anterior intercostal, which perforates the diaphragm, and forms the semilunar ganglious, from which nerves pass to all the abdominal viscera. They also form in the abdomen ten peculiar plexuses, distinguished by the name of the viscus to which they belong, as the coliac, splenic, hepatic, superior, middle, and lower, mesenteric, two renal, and two spermatic plexuses. The posterior intercostal nerve gives accessory branches about the pelvis and ischiatic nerve, and at length terminates.

INTERCOSTAL VEINS. The intercostal veins empty their blood into the vena

INTERCURRENT FEVERS. Those which happen in certain seasons only, are called stationary; but others are called, by Sydenham, intercurrents.

INTERCUS. (From inter, between, and cutem, the skin.) A dropsy between the skin and the flesh. See Anasarca.

INTERDENTIUM. (From inter, between, and dens, a tooth.) The intervals between teeth of the same order.

INTERDIGITUM. (From inter, between, and digitus, a toe, or finger.) A corn betwixt the toes, or wart betwixt the fingers.

INTERFAMINEUM. (From inter, tween, and femen, the thigh.) The perinæum, or space between the anus and pudendum.

(From inter, INTERLUNIUS MORBUS, between, and luna, the moon; because it was supposed to affect those who were born in the wane of the moon. The epilepsy.

Intermittent fever. See Febris intermit-

INTERNUNTII DIES. (From internuncio, to go between.) Applied to critical days, or such as stand between the increase of a disorder and its decrease.

INTEROSSEI MANUS. (Interosseus musculus; from inter, between, and os, the bone.) There are small muscles situated between the metacarpal bone, and extending from the bones of the carpus to the fingers. They are divided into internal and external; the former are to be seen only on the palm of the hand, but the latter

three in number. The first, which Albinus names posterior indicis, arises tendinous and fleshy from the basis and inner part of the metacarpal bone of the fore-finger, and likewise from the upper part of that which supports the middle-tinger. Its tendon passes over the articulation of this part of these bones with the fore-finger, and, uniting with the tendinous expansion that is sent off from the extensor digitorum communis, is inserted into the posterior convex surface of the first phalanx of that finger. The second and third, to which Albinus gives the names of prior annularis, and interosseus auricularis, arise, in the same manner, from the basis of the outsides of the metacarpal bones that sustain the ring-finger and the little-finger, and are inserted into the outside of the tendinous expansion of the extensor digitorum communis that covers each of those fingers. These three muscles draw the fingers into which they are inserted, towards the thumb. The interossei externi are four in number, for among these is included the small muscle that is situated on the outside of the metacarpal bone that supports the fore-finger. Douglas calls it extensor tertii internodii indicis, and Winslow semi interosseus indicis. Albinus, who describes it among the interossei, gives it the name of prior indicis. This first interesseus externus arises by two tendinous and fleshy portions. One of these springs from the upper half of the inner side of the first bone of the thumb, and the other from the ligaments that unite the os trapezoides to the metacarpal bone of the fore-finger, and likewise from all the outside of this latter bone. These two portions unite as they descend, and terminate in a tendon, which is inserted into the outside of that part of the tendinous expansion from the extensor digitorum communis that is spread over the poserior convex surface of the fore-finger. The second, to which Albinus gives the name of prior medii, is not quite so thick as the last-described muscle. It arises by two heads, one of which springs from the inner side of the metacarpal bone of the fore-finger, chiefly towards its convex surface, and the other arises from the adjacent ligaments, and from the whole outer side of the metacarpal bone that sustains the middle-finger. These two portions unite as they descend, and terminate in a tendon, which is inserted, in the same manner as the preceding muscle, into the outside of the tendinous expansion that covers the posterior part of the middle finger. The third belongs likewise to the middle-finger, and is therefore named pos-terior medii by Albinus. It arises, like the last-described muscle, by two origins, which spring from the roots of the metaare conspicuous both on the palm and back carpal bones of the ring and middle fingers,

and from the adjacent ligaments, and is inserted into the inside of the same tendinous expansion as the preceding muscle. The fourth, to which Albinus gives the name of posterior annularis, differs from the two last only in its situation, which is between the metacarpal bones of the ring and little fingers. It is inserted into the inside of the tendinous expansion of the extensor digitorum communis, that covers the posterior part of the ring-finger. All these four muscles serve to extend the fingers into which they are inserted, and likewise to draw them inwards, towards the thumb, except the third, or posterior medii, which, from its situation and insertion, is calculated to pull the middle finger outwards.

INTEROSSEI PEDIS. These small muscles, in their situation between the metatarsal bones, resemble the interossei of the hand, and, like them, are divided into internal and external. The interossei pedis interni are three in number. They arise tendinous and fleshy, from the basis and inside of the metatar al bones of the middle, the third, and the little toes, in the same manner as those of the hand, and they each terminate in a tendon that runs to the inside of the first joint of these toes, and from thence to their upper surface, where it loses itself in the tendinous expansion that is sent off from the extensors. Each of these three muscles serves to draw the toe into which it is inserted towards the great-toe. The interessei externi are four in number. The first arises tend nous and fleshy from the outside of the root of the metatarsal bone of the great-toe, from the os cuneiforme internum, and from the root of the inside of the metatarsal bone of the fore-toe, Its tendon is inserted into the inside of the tendinous expansion that covers the back part of the toes. The second is placed in a similar manner between the metatarsal bones of the fore and middle toes, and is inserted into the outside of the tendinous expansion on the back part of the fore-toe. The third and fourth are placed between the two next metatarsal bones, and are inserted into the outside of the middle and third toes. The first of these muscles draws the fore-toe inwards towards the great-toe. The three others pull the toes, into which they are inserted, outwards. They all assist in extending the

INTERPELLATUS MORBUS. (From inpello, to interrupt.) In Paracelsus it is a disease attended with irregular or uncertain paroxysms.

INTERPOLATUS DIES. (From interpolo, to renew.) In Paracelsus, these are the days interpolated betwixt two paroxysms.

INTERSCAPULIUM. (From inter, be-

tween, and scapula, the shoulder-blade.) That part of the spine which lies between the shoulders.

INTERSEPTUM. (From inter, between, and septum, an inclosure.) The uvula and the

septum narium.

INTERSPINALES COLLI. (Interspinales musculi; from inter, between, and spina, the spine.) The fleshy portions between the spinous processes of the neck, that draw these processes nearer to each other.

INTERSPINALES DORSI ET LUM- BORUM. These are rather small tendons than muscles, that connect the spinal and

transverse processes.

INTERTRANSVERSALES LUMBO-RUM. Four distinct small bundles of flesh, which fill up the spaces between the transverse processes of the vertebræ of the loins, and serve to draw them towards each other.

INTERTRIGO. (From inter, between, and tero, to rub) An excoriation about the anus, groins, axilla, or other parts of the body, attended with inflammation and moisture. It is most commonly produced by the irritation of the urine, from riding, or

some acrimony in children.

INTESTINES (Intestina; from intus, within.) The convoluted membranous tube that extends from the stomach to the anus; receives the ingested food; retains it a certain time; mixes with it the bile and pancreatic junces; propels the chyle into the lacteals, and covers the faces with mucus; is so called. The intestines are situated in the cavity of the abdomen, and are divided into the small and large, which have, besides their size, other circumstances of distinction.

The small intestines are supplied internally with folds, cailed valvulæ conniventes, and have no bands on their external surface. The large intestines have no folds internally, and are supplied externally with three strong muscular bands, which run parallel upon the surface, and give the intestines a saccated appearance; and they have also small fatty appendages, called

appendiculæ epiploicæ.

The first portion of the intestinal tube, for about the extent of twelve fingers' breadth, is called the duodenum; it lies in the epigastric region; makes three turnings, and between the first and second flexure receives, by a common opening, the parcreatic duct, and the ductus communis choledo hus. It is in this portion of the intestines that chylification is chiefly performed. The remaining portion of the small intestines is distinguished by an imaginary division into the jejunum and ileum.

The jejunum, which commences where the duodenum ends, is situated in the umbilical region, and is mostly found empty; hence its name; it is every where covered with red vessels, and, about an hour and an

half after a meal, with lacteals.

The *ileum* occupies the hypogastric region and the pelvis; is of a more pallid colour than the former, and terminates by a transverse opening into the large intestines, which is called the valve of the deum, valve of the excum, or the valve of Tulpius.

The beginning of the large intestines is firmly tied down in the right iliac region, and for the extent of about four fingers' breadth is called the cæcum, having adhering to it a worm-lke process, called the processus ceci vermiformis, or appendicula The great intestine c.eci vermiformis. then commences colon, ascends towards the liver, passes across the abdomen, under the stomach, to the left side, where it is contorted like the letter S, and descends to the pelvis: hence it is divided in this course into the ascending portion, the transverse arch, and the sigmoid flexure. When it has reached the pelvis, it is called the rectum, from whence it proceeds in a straight line to the anus.

The intestinal canal is composed of three membranes, or coats; a common one from the peritoneum, a muscular coat, and a villous coat, the vill being formed of the fine terminations of arteries and nerves, and the origins of lacteals and lymphatics. The intestines are connected to the body by the mysentery; the duodenum has also a peculiar connecting cellular substance, as has likewise the colon and rectum, by whose means the former is firmly accreted to the back, the colon to the kidneys, and the latter to the os coccygis, and in women to the vagina. The e naming portion of the tube is loose in the cavity of the abdomen. The arteries of this canal are branches of the superior and inferior mesenteric, and the dundenal. The veins evacuate their blood into the vena portæ. The nerves are branches of the eighth pair and intercostals. The lacteal vessels, which origmate principally from the j junum, proceed to the glands in the mesentery.

Intuicatus (From intrico, to entangle; so cath d from its intricate folds.) A mus-

cle of the ear.

INTRINSECT. (From intra, within, and cecus, towards) Painful disorders of the intern I parts.

INTROCESSIO. (From introcedo, to go in.)
Depressio. A depression or sinking of any

part inwards.

INTUS-SUSCEPTION. (Intus-susceptio and intro-susceptio; trom intus, within, and susceptio, to receive.) A disease of the intestinal tube, and most frequently of the small intestines; it consists in a portion of gut passing for some length within another portion.

INTERES. (From in, and tuba, a hollow

instrument, so named from the hollowness of its stalk.) See Endivia.

INULA. (Contracted or corrupted from helenium, nasser, fabled to have sprung from the tears of Helen.) 1. The name of a genus of plants in the Lunnan system. Class, Syngenesia. Order, Polygamia superflua.

2. The herb elecampane.

Inula, common. See Enula campana.

INULA DYSENTERICA. The systematic name of the lesser mula. See Conyza media.

INULA HELENIUM. The systematic name of the elecampane. See *Enula cambana*.

INUSTION. (From in, and ure, to burn.) Is sometimes used for hot and dry seasons; but most commonly by surgeons for the operation of the cautery.

INVERECUNDUM os. (From in, not, and verecundus, modest.) A name of the os frontis, from its being regarded as the seat

of impudence.

Inversion of the uterus. See Uterus, in-

version of.

INVOLUCRUM. (From in, and volvo, to wrap up; because parts are enclosed by it.) A name of the pericardium; also a name of the membrane which covers some of the viscera.

lodge. (From 105, brass.) Verdigrise. Green matter thrown off by vomiting.

IONIS. (From 129, a violet.) A carbuncle of a violet colour.

INSTRUCE. (From 109, a violet, and  $\alpha y$ - $\theta y$ , a flower.) A hard pimple in the face,
of a violet colour.

lotacismus. (From 1672, the Greek letter 1) A defect in the tongue, or organs of speech, which renders a person incapable of pronouncing his letters.

lovi. A restorative alimentary liquor, prepared in Japan. It is made from the gravy of half-roasted beef; but, as to the

rest, it is kept a secret.

The plant from which this valuable root is obtained was long unknown; it was said by some writers to be the Psychotria emetica; class Pentandria; order Monogyma: by others, the Ivola ipecacuanha, a syngenesious plant of the order Monogymia. It is now ascertained to be neither, but a small plant called Collicocca ipecacuanha. There are three sorts of ipecacuan to be met with in our shops, viz. the ash-coloured or grey, the brown, and the white.

The ash-coloured is brought from Peru, and is a small wrinkled root, bent and contorted into a great variety of figures, brought over in short pieces, full of wrinkled and deep circular fissures, down to a small white woody fibre that runs in the middle of each piece: the cortical part is compact, brittle, looks smooth, and re-

sinous upon breaking: it has very little smell; the taste is bitterish and subacrid, covering the tongue, ss it were, with a kind of mucilage.

The brown is small, somewhat more wrinkled than the foregoing; of a brown or blackish colour without, and white within:

this is brought from Brazil.

The white sort is woody, and has no wrinkles, nor any perceptible bitterness in taste. The first, the ash-coloured or grey ipecacuan, is that usually preferred for medicinal use. The brown has been some-times observed, even in a small dose, to produce violent effects. The white, though taken in a large one, has scarce any effect Experience has proved that this at all. medicine is the safest emetic with which we are acquainted, having this peculiar advantage-that, if it does not operate by vomit, it readily passes off by the other Ipecacuan was first introemunctories. duced as an infallible remedy against dysenteries and other inveterate fluxes, as diarrhoa, menorrhagia, leucorrhoa, &c. and also in disorders proceeding from obstructions of long standing; nor has it lost much of its reputation by time: its utility in these cases is thought to depend upon its restoring perspiration. It has also been successfully employed in spasmodic asthma, catarrhal and consumptive cases. Nevertheless, its chief use is as a vomit, and in small doses, joined with opium, as a diaphoretic. The officinal preparations are the pulvis ipecacuanha compositus, and the vinum ipecacuanha.

IQUETAIA. The inhabitants of the Brazils give this name to the Scrophularia aquatica, which is there celebrated as a correc-

tor of the ill flavour of senna.

IRACUNDUS. (From ira, anger; so called because it forms the angry look.) A mus-

cle of the eye.

IRIS. (Á rainbow; so called because of the variety of its colours.) 1. The anterior portion of the choroid membrane of the eye, which is perforated in the middle by the pupil. It is of various colours. The posterior surface of the iris is termed the arma.

2. The flower de-luce is also called iris, from the resemblance of its flowers to the

ainbow.

3. The name of a genus of plants in the Linnæan system. Class, Triandra. Order,

Monogynia.

IRIS FLORENTINA. Florentine orris, or iris. The root of this plant, Iris florentina of Linnæus:—corollis barbatis, canle foliis altiore subbifloro, floribus sessilibus; which is indigenous to Italy, in its recent state is extremely acrid, and, when chewed, excites a pungent heat in the mouth, that continues several hours: on being dried, this acrimony is almost wholly dissipated;

the taste is slightly bitter, and the smell agreeable, and approaching to that of violets. The fresh root is cathartic, and for this purpose has been employed in dropsies. It is now chiefly used in its dried state, and ranked as a pectoral and expectorant, and hence has a place in the trochissi amyli of the pharmacopæias.

Iris, Florentine. See Iris Florentina.
IRIS GERMANICA. The systematic name of the flower-de-luce. See Iris nostras.

IRIS NOSTRAS. Common iris, or orris. Flower-de-luce. This plant is the Iris germanica of Linnœus:—corollis barbatis, caude folis altioni multifloro, floribus inferioribus pedunculatis. The fresh roots have a strong disagreeable smell, and an acrid nauseous taste. They are powerfully cathartic, and are given in dropsical diseases, where such remedies are indicated.

IRIS PALUSTRIS. Gladiolus luteus. Acorus vulgaris. Yellow water flag. This indigenous plant, Iris pseudacorus :- imberbis, foliis ensiformibus, petalis alternis, stigmatibus minoribus, is common in marshes, and on the banks of rivers. It formerly had a place in the London Pharmacopæia, under the name of gladiolus luteus. root is without smell, but has an acrid styptic taste, and its juice, on being snuffed up the nostrils, produces a burning heat in the nose and mouth, accompanied by a copious discharge from these organs; hence it is recommended both as an errhine and sialagogue. Given internally, when perfectly dry, its adstringent qualities are such as to cure diarrhoas The expressed juice is likewise said to be an useful application to serpiginous eruptions and scrofulous tumours.

IRIS PSEUDACORUS. The systematic name of the yellow water-flag. See Iris Pa-

Irish slate. See Lapis Hybernicus.

IRON. Ferrum. Of all the metals, there is none which is so copiously and so variously dispersed through nature as iron. In animals, in vegetables, and in all parts of the mineral kingdom, we detect its presence. Mineralogists are not agreed with respect to the existence of native iron, though immense masses of it have been discovered, which could not have been the products of art; but there is much in favour of the notion that these specimens have been extracted by subterraneous fire. A mass of native iron, of 1600 pounds weight, was found by Pallas, on the river Denisei, in Siberia; and an-other mass of 300 pounds was found in Paraguay, of which specimens have been distributed every where. A piece of native iron, of two pounds weight, has been also met with at Kamsdorf, in the territories of Neustadt, which is still preserved These masses evidently did not there.

IRON. 417

originate in the places where they were found.

There are a vast variety of iron ores; they may, however, be all arranged under the following genera; namely, sulphurets, carburets, oxyds, and salts of iron. The surphurets of iron from the ores, called pyrites, of which there are many varieties. Their colour is, in general, a straw-yellow, with a metallic lustre. They are often amorphous, and often also crystallized. Iron ores of this kind are known by the name of mundick. Iron, in the state of a carburet, forms the graphite of Werner, (plumbago.) This mineral occurs in kidney-form tumps of various sizes. Its colour is a dark iron-grey, or brownish black; when cut, blueish grey. It has a metallic lustre. Its texture is fine grained. It is very brittle. The combination of iron with oxygen is very abundant. The common magnetic iron stone, magnetical pyrites, or load-stone, belongs to this class: as does specular iron ore, and all the different ores called hematites, or blood-stone. Iron, combined with silex, constitutes emery. Iron, united to carbonic acid, exists in the sparry iron ore. Joined to arsenic acid it exists in the ores called arseniate of iron, and arseniate of iron and copper.

Properties of iron.-Iron is distinguished

from every other metal by its magnetical properties. It is attracted by the magnet, and acquires, under various conditions, the property of magnetism. Pure iron is of a whitish grey, or rather blueish colour, very slightly livid; but when polished, it has a great deal of brilliancy. Its texture is either fibrous, fine grained, or in dense plates. Its specific gravity varies from 76 to 7.8 It is the hardest and most elastic of all the metals. It is extremely ductile, and may therefore be drawn into wire as fine as a human hair; it is also more tenacious than any other metal, and consequently yields with equal facility to pressure. It is extremely infusible, and, when not in contact with the fuel, it cannot be melted by the heat which any furnace can excite; it is, however softened by heat, still preserving its ductility; this constitutes the valuable property of welding. It is very dilatable by heat. It is the only metal which takes fire by the col-I sion of flint. Heated by the contact of air it becomes oxydated. If intensely and briskly heated, it takes fire with scintillation, and becomes a black oxyd. It combines with carbon, and forms what is called steel. It combines with phosphorus in a direct and in an indirect manner. and unites with sulphur readily, by mixture in the cold with water, and by fusion. It decomposes water in the cold slowly, but

of the metallic oxyds. All acids act upon

Very concentrated sulphuric acid

has little or no effect upon it, but when diluted it oxydates it rapidly. The tric acid oxydates it with great vehemence. Murrate of ammonia is decomposed by it. Nitrate of potash detonates very vigorously with it. Iron is likewise dissolved by alkaline sulphurets. It is capable of combining with a number of metals. It does not unite with lead or bismuth, and very feebly with mercury. It detonates by percussion with the oxygenated muriates.

Method of obtaining iron.-The general process, by which iron is extracted from its ores, is first to roast them by a strong heat, to expel the sulphur, carbonic acid, and other mineralizers, which can be separated by heat. The remaining ore, being reduced to small pieces, is mixed with charcoal, or coke; and is then exposed to an intense heat, in a close fornace, excited by bellows; the oxygen then combines with the carbon, forming carbonic acid gas during the process, and the oxyd is reduced to its metallic state. There are likewise some fluxes necessary, in order to facilitate the separation of the melted metal. The matrix of the iron ore is generally either argillaceous or calcarcous, or sometimes a portion of silecious earth; but whichever of these earths is present, the addition of one or both of the others makes a proper flux. These are therefore added in due proportion, according to the nature of the orcs; and this mixture, in contact with the fuel, is exposed to a heat sufficient to reduce the oxyd to its metallic state.

The metal thus obtained, and called smelted, pig, or cast, iron, is far from being pure, always retaining a considerable quantity of carbon and oxygen, as well as several heterogeneous ingredients. According as one or other of these predominates, the property of the metal differs. Where the oxygen is present in a large proportion, the colour of the iron is whitish grey, it is extremely brittle, and its fracture exhibits an appearance of crystallization: where the carbon exceeds, it is of a dark grey, inclining to blue, or black, and is less brittle. The former is the white, the latter the black, crude iron of commerce. The grey is intermediate to both. In many of these states, the iron is much more fusible than when pure; hence it can be fused and cast into any form; and when suffered to cool slowly, it crystalizes in octahedra; it is also much more bratle, and cannot therefore be either flattened under the hammer, or by the laminating

To obtain the iron more pure, or to free it from the carbon with which it is combined in this state, it must be refined, by subjecting it to the operations of melting and forging. By the former, in which the metal is kept in fusion for some time, and constantly kneaded and stirred, the quan-

SH

tity of carbon and oxygen it contains are combined, and the produced carbonic acid gas is expelled: the metal at length becomes viscid and stiff; it is then subjected to the action of a very large hammer, or to the more equal, but less forcible, pressure of large rollers, by which the remaining oxyd of iron, and other impurities, not consumed by the fusion, are pressed out. The iron is now no longer granular nor crystalized in its texture; it is fibrous, soft, ductile, malleable, and totally infusible. It is termed forged, wrought, or bar, iron, and is the metal in a purer state, though far from being absolutely pure.

The general medicinal virtues of iron, and the several preparations of it, are to constringe the fibres, to quicken the circulation, to promote the different secretions in the remoter parts, and at the same time to repress inordinate discharges into the intestinal tube. By the use of chilybeates, the pulse is very sensibly raised; the colour of the face, though before pale, changes to a florid red; the alvine, urinary, and cuticular excretions, are increased. Fetid eructations, and black coloured faces, are marks of their taking due effect.

When given improperly, or to excess, iron produces head-ache, anxiety, heats the body, and often causes hæmorrhages, or even vomiting, pains in the stomach,

spasms, and pains of the bowels.

Iron is given in most cases of debility and relaxation. In passive hamorrhages. In dyspepsia, hysteria, and chlorosis. In most of the cachexia; and it has lately been recommended as a specific in cancer. In general debility, produced by disease, or excessive hamorrhages. Where either a preternatural discharge, or suppression of natural secretions, proceeds from a langour, or sluggishness of the fluids, and weakness of the solids, this metal, by increasing the motion of the former and the strength of the latter, will suppress the flux, or remove the suppression; but where the circulation is already too quick, the solids too tense and rigid, where there is any stricture, or spasmodic contraction of the vessels, iron, and all thepreparations of it, will aggravate both diseases. Iron probably has no action on the body when taken into the stomach, unless it be oxydized. But during its oxydisement, hydrogen gas is evolved, and accordingly we find that fœtid eructations are considered as a proof of the medicine having taken effect. It can only be exhibited internally in the state of filings, which may be given in doses from five to twenty grains. Iron wire is to be preferred for pharmaceutical preparations, both because it is the most convenient form, and because it is the

IRRITABILITY. (From irrito, to provoke.) Vis insita of Haller. Vis vitalis of Goeter. Oscilliation of Boerhaave. Tonic power of Stahl. Muscular power of Bell. Inherent power of Cullen. The contractility of muscular fibres, or a property peculiar to muscles, by which they contract upon the application of certain stimuli, without a consciousness of action. This power may be seen in the tremulous contraction of muscles when lacerated, or when entirely separated from the body in operations. Even when the body is dead to all appearance, and the nervous power is gone, this contractile power remains till the organization yields, and begins to be dissolved. It is by this inherent power that a cut muscle contracts, and leaves a gap; that a cut artery shrinks and grows stiff after death. This irritability of muscles is so far independent of nerves, and so little connected with feeling, which is the province of the nerves, that, upon stimulating any muscle by touching it with caustic, or irritating it with a sharp point, or driving the electric spark through it, or exciting with the metallic conductors, as those of silver, or zinc, the muscle instantly contracts, although the nerve of that inuscle be tied; although the nerve be cut so as to separate the muscle entirely from all connection with the system; although the muscle be separated from the body; although the creature upon which the experiment is performed may have lost all sense of feeling, and have been long apparently dead. Thus a muscle, cut from the limb, trembles and palpitates a long time after; the heart, separated from the body, contracts when irritated; the bowels, when torn from the body, continue their peristaltic motion, so as to roll upon the table, ceasing to answer to stimuli only when they become stiff and cold,; and too often, in the human body, the vis insita loses the ex-citing power of the nerves, and then palsy ensues; or, losing all governance of the nerves, the vis insita, acting without the regulating power, falls into partial or general convulsions. Even in vegetables, as in the sensitive plant, this contractile power lives. Thence comes the distinction between the irritability of muscles and the sensibility of nerves; for the irritability of the irritabi tability of muscles survives the animal, as when it is active after death; survives the life of the part of the feelings of the whole system, as in universal palsy, where the vital motions continue entire and perfect, and where the muscles, though not obedient to the will, are subject to irregular and violent actions; and it survives the connection with the rest of the system, as when animals, very tenacious of life, are cut into parts: but sensibility, the property of the nerves, gives the various modifications of sense, as vision, hearing, and the rest; gives also the general sense of pleasure or pain, and makes the system, according to its various conditions, feel vigorous and healthy, or weary and low. And thus the eye feels and the skin feels: but their appointed stimuli produce no motions in these parts; they are sensible, but not irritable. The heart, the intestines, the urinary bladder, and all the muscles of voluntary motion, answer to stimuli with a quick and forcible contraction; and yet they hardly feel the stimuli by which these contrac-tions are produced, or, at least, they do not convey that feeling to the brain. There is no consciousness of present stimulus in those parts which are called into action by the impulse of the nerves, and at the command of the will: so that muscular parts have all the irritability of the system, with but little feeling, and that little owing to the nerves which enter into their substance; while nerves have all the sensibility of the system, but no motion.

The discovery of this singular property belongs to our countrymen Glysson; but Baron Haller must be considered as the first who clearly pointed out its existence, and proved it to be the cause of muscular

motion.

The laws of irritability, according to Dr. Crichton, are, 1. After every action in an irritable part, a state of rest, or cessation from motion, must take place before the irritable part can be again incited to action. If, by an act of volition, we throw any of our muscles into action, that action can only be continued for a certain space of time; the muscle becomes relaxed, notwithstanding all our endeavours to the contrary, and remains a certain time in that relaxed state, before it can be again thrown into action. 2. Each irritable part lias a certain portion or quantity of the principle of irritability which is natural to it, part of which it loses during action, or from the application of stimuli. 3. By a process wholly unknown to us, it regains

this lost quantity, during its repose, or state of rest. In order to express the different quantities of irritability in any part, we say that it is either more or less redundant, or more or less defective. It becomes redundant in a part when the stimuli which are calculated to act on that part are withdrawn or withheld for a certain length of time, because then no action can take place; while, on the other hand, the application of stimuli causes it to be exhausted, or to be deficient, not only by exciting action, but by some secret influence, the nature of which has not yet been detected; for it is a circumstance extremely deserving of at ention, that an irritable part, or body, may be suddenly deprived of its irritability by powerful stimuli, and yet no apparent cause of muscular or vascular action takes place at the time. A certain quantity of spirits, taken at once into the stomach, kills almost as instantaneously as lightning does: the same thing may be observed of some poisons, as opium, distilled laurel-water, the juice of the cerbera ahova, &c. 4. Each irritable part has stimuli which are peculiar to it; and which are intended to support its natural action: thus, blood, which is the stimulus proper to the heart and arteries, if, by any accident, it gets into the stomach, produces sickness, or vomiting. the gall, which is the natural stimulus to the gall-bladder, duct and duodenum, is by any aecident effused into the cavity of the peritoneum, it excites too great action of the vessels of that part, and induces inflammation. The urine does not irritate the tender fabric of the kidneys, ureters, or bladder, except in such a degree as to preserve their healthy action; but if it be. effused into the cellularimembrane, it brings on such a violent action of the vessels of these parts, as to produce gangrene. Such stimuli are called habitual stimuli of parts. 5. Each irritable part differs from the rest in regard to the quantity of irritability which it possesses. This law explains to us the reason of the great diversity which we observe in the action of various irritable parts; thus the muscles of voluntary motion can remain a long time in a state of action, and if it be continued as long as possible, another considerable portion of time is required before they regain the irritability they lost; but the heart and arteries have a more short and sudden action. and their state of rest is equally so. The circular muscles of the intestines have also a quick action and short rest. The mrinary bladder does not fully regain the irritability it loses during its contraction for a considerable space of time; the vessels which separate and throw out the menstrual discharge act, in general, for three or four days, and do not regain the irritability they lose for a lunar month. 6. All stimul iproduce action in proportion to their irritating powers. As a person approaches his hand to the fire, the action of all the vessels in the skin is increased, and it glows with heat; if the hand be approached still nearer, the action is increased to such an unusual degree as to occasion redness and pain; and if it be continued too long, real inflammation takes place; but if this heat be continued, the part at last loses its irritability, and a sphacelus or gangrene ensues. 7. The action of every stimulus is in an inverse ratio to the frequency of its application. A small quantity of spirits taken into the stomach, increases the action of its muscular coat, and also of its various vessels, so that digestion is thereby facilitated. If the same quantity, however, be taken frequently, it loses its effect. In order to produce the same effect as at first, a larger quantity is necessary: and hence the origin of dramdrinking. 8 The more the irritability of a part is accumulated, the more that part is disposed to be acted upon. It is on this account that the activity of all animals, while in perfect health, is much livelier in the morning that at any other part of the day; for, during the night, the irritability of the whole frame, and especially that of the muscles destined for labour, viz. the inuscles for voluntary action, is re-accumul.ted. The same law explains why digestion goes on more rapidly the first hour after food is swallowed, than at any other time; and it also accounts for the great danger that accrues to a famished person upon first taking in food, 9. If the stimuli which keep up the action of any irritable body be withdrawn for too great a length of time, that process on which the formation of the principle depends is gradually diminished, and at last entirely destroyed. When the irritability of the system is too quickly exhausted by heat, as is the case in certain warm climates, the application of cold invigorates the frame, because cold is a mere diminution of the overplus of that stimulus which was causing the rapid consumption of the principle. Under such or similar circumstances, therefore, cold is a tonic remedy; but if, in a climate naturally cold, a person were to go into a eld bath, and not soon return into a warmer atmosphere, it would destroy life just in the same manner as many poor people who have no comfortable dwellings are often destroyed from being too long exposed to the cold in winter. Upon the first application of cold the irritability is accumulated, and the vascular system therefore is exposed to great action; but, after a certain time, all action is so much diminished, that the process, whatever it be, on which the formation of eases are, an inflammation of the urethra,

the irritable principle depends, is entirely lost. For further information on this interesting subject, see Dr. Crichton on Mental Derangement,

IRRITATION. Irritatio. The action

produced by any stimulus.

Isca. A sort of fungous exerescence of the oak, or of the hazel, &c. The antients used it as the moderns used mova.

ISCHÆMON. (From 15χω, to restrain, and aima, blood.) A name for any medicine which restrains or stops bleeding.

ISCHEMUM, A species of Andropogon, ISCHIAS. (Ioxias: from ioxior, the hip.) Sciatica. A rheumatic affection of the Inp-joint. See Rl.eumatismus.

ISCHIATOCELE. (From 10x10), the hip, and waxa, a rupture.) Ischiocele. intestinal rupture, through the sciatic liga-

ments.

Ischio-cavernosus. See Erector penis.

ISCHIUM. (From 1721s, the loin; so named because it is near the loin.) A bone of the pelvis of the fœtus, and a part of the os innominatum of the adult. See Innominatum os.

ISCHNOPHONIA. (From 15xvos, slender, and own, the voice.) A shrillness of the voice; but more frequently an hesitation of speech, or stammering; it is the psellismus hæsitans of Cullen.

Iscauretica. (From 10x8g1x, a suppression of the urme.) Mediemes which relieve

a suppression of the urine,

ISCHURIA. (From 1000, to restrain, and sgov, the urine.) A suppression of urine. A genus of disease in the clsss locales and order epischeses of Cullen. There are four species of ischuria.

1. Ischuria renalis, coming after a disease of the kidneys, with a troublesome sense

of weight in that part.

2. Ischuria ureterica, a disease of the kidneys, a sense of pain or uneasines in the course of the ureters.

3. Ischuria vesicalis, a frequent desire to make water, with a swelling of the hypogastrium, and pain at the neek of the bladder.

4. Ischuria urethralis, a frequent desire to make water, with a swelling of the hypogastrium, and pain of some part of the nrethra.

When there is a frequent desire of making water, attended with much difficulty in voiding it, the complaint is called a dysury, or strangury; and when there is a total suppression of urine, it is known by the name of an ischury. Both ischuria and dysuria are distinguished into acute, when arising in consequence of inflammation, and chronic, when proceeding from any other eause, such as calenlus, &c.

The causes which give rise to these dis-

occasioned either by venereal sores, or by a use of aerid injections, tumour or ulcer of the prostate gland, inflammation of the bladder or kidneys, considerable enlargements of the hamorrhoidal veins, a lodgement of indurated faces in the rectum, spasm at the neck of the bladder, the absorption of cantharides applied externally, or taken internally, and excess in drinking either spirituous or vinous liquors; but particles of gravel sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. Gouty matter falling on the neck of the bladder will sometimes

occasion these complaints. In dysury there is a frequent inclination to make water, attended with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceeds from a calculus in the kidney, or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the toins and region of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and a stream of water will either be divided into two, or be discharged in a twisted manner, not unlike a cork-screw. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, imattended with any acute pain, may readily be felt in the perinaum, or by introducing the finger in ano.

Dysury is seldom attended with much danger, unless, by neglect, it should terminate in a total obstruction. Ischury may always be regarded as a dangerous complaint, when it continues for any length of time, from the great distention and often consequent inflammation which cusue. In those cases, where neither a bouger ner a catheter can be introduced; the event, in all probability, will be fatal, as few

patients will submit to the only other means of drawing off the urine before a considerable degree of inflammation and tendency to gangrene have taken place.

Isinglass. See Ichthyocolla.

ISLANDICUS MUSCUS. See Lichen islandicus.

ISOCHRONOS. (From 1005, equal, and X50005, time.) Preserving an equal distance of time between the beats; applied to the pulse.

Isochates. (From 1505, equal, and xegarromi.) Wine mixed with an equal quantity of water.

Isonronus. (From 1000, equal, and Ser-180 run.) The same as Isochronos. Isopraus. (From 1000, equal, and 1000,

lsorraum. (From 1005, equal, and 709, fire, so named from its flame-coloured flower.) The herb aquilegia.

Isoronus. (From 1005, equal, and 70005, extension.) Applied to fevers which are of equal strength during the whole of the

paroxysm.

ISSUE. Fonticulus. An artificial ulcer, intended as a remedy on certain morbid affections, by producing a discharge of purulent matter from different parts of the body.

Istimion. (From 1σθμος, a narrow piece of land between two seas.) The narrow passage between the mouth and

gullet : the fances.

ISTINUS VIEUSSENII. The ridge surrounding the oval lossa, or remains of the foramen ovale, in the right auricle of the human heart.

ITHMOIDES. Falsely, for Ethmoides. ITHMERARIEM. (From itinero, to travel.) The catheter; also a staff used in cutting for the stone; it is thus named by Hildanus.

IVA PECANGA. See Sarsaparilla.

Ivy. See Hedera arborea.

Ivy, ground. See Hedera terrestris. Ivy-gum. See Gummi hederæ.

IXIA. (From 1500, glue.) A name of the carlina, from its viscous jnice. Also a preternatural distention of the veins, from 150,000, to proceed from.

IXINE. See Carlina gummifera.

J.

JACEA. (Quia prodest hominibus tristitia jacentibus; because it resists sorrow; or from 120,021, to heal.) The herb pansey, or hear's-case.

Jack by the hedge. See Alliaria.

Jeonnea. (Named because it was dedicated to St. James, or because it was directed to be gathered about the teast of

St. James.) St. James's wort. Ragwort. Senecto jacobea of Linnaus. The leaves of this common plant have a roughish, bitter, sub-acrid taste, extremely nauseous. A decoction is said to have been of infinite service in the circ of epidemic camp dysentery.

Jalap. See Jalapium. JALAPA. See Jalapium.

JALAPIUM. (From Chalapa, or Xala-

pa, in New Spain, whence it is brought.) Mechoacanna nigra. Jalap. The plant from which this root is obtained is the Convolvulus jalapa :-- caule volubili ; foliis ovatis, subcordatis, obtusis, obsolete repandis, subtus vilosis; pedunculis unifloris: ana ive of South America. In the shops, the root is found both cut into slices and whole, of an oval shape, solid, ponderous, blackish on the outside, but grey within, and marked with several dark veins, by the number of which, and by its hardness, heaviness, and dark colour, the goodness of the root is to be estimated. It has scarcely any smell, and very little taste, but to the tongue, and to the throat, manifests a slight degree of pungency. The medicinal activity of jalap resides principally, if not wholly, in the resin, which, though given in small doses, occasions violent tormina. The root, powdered, is a very common, efficacious, and safe purgative, as daily experience evinces; but, according as it contains more or less resin, its effects must of course vary. In large doses, or when joined with calomel, it is recommended as an anthelmintic and hydrogogue. In the pharmacopæias, this root is ordered in the form of tincture and extract; and the Edinburgh College directs it also in powder, with twice its weight of ohrystals of tartar.

JALAPA ALBA. See Mechoacanna. Jamaica bark. See Chinchini caribaa. Jamaica pepper. See Pimenta.

JAMBLICI SALES. A preparation with sal-ammoniac, some aromatic ingredients, &c. so called from Jamblichus, the inventor

JANITOR. (From janua, a gate.) pylorus, so called from its being, as it were, the door or entrance of the intestines.

Japan earth. See Catechu.

JARGON. Terra circona. Te Terra zerconia. A primitive earth, lately found in the precious stone called jargon, or hyacinth of the island of Ceylon. When calcined, it has a white colour, is exceedingly heavy, and rough to the touch, has no taste, and is insoluble in water.

JASMINUM. Jasminum; 120 µ1005: from jasmen, Arab. or from 101, a violet, and 152san, odour, on account of the fine odour of the flowers.) 1. The name of a genus of plants in the Linnaan system. Class, Di-

andria. Order, Monogynia.

2. The pharmacopæial name of the jessaminc. The flowers of this beautiful plant, the Jasminum officinale of Linnæus, have a very fragrant smell, and a bitter taste. They afford, by distillation, an essential oil, which is much esteemed in Italy to rub paralytic limbs, and in the cure of rheumatic pains.

JASMINUM OFFICINALE. The systematic name of the jessamine-tree. See Jas-

minum.

JATRALEIPTES. (From 12700s, a physician, and αλειφω, to anoint.) One who undertakes to cure distempers by external unction and friction: Galen makes mention of such in his time, particularly one Diotas; and Priny informs us, that this was first introduced by Prodicus of Selymbria, who was a disciple of Esculapius.

(From 127gos, a phy-JATROCHYMICUS. sician, and xumia, chymistry.) Chymiaster. A chymical physician, who cures by means

of chymical medicines.

JATROLIPTICE. (From ιατρος, a physician, and λειτω, to anoint.) The method of curing diseases by unction and fric-

JATROPHA. The name of a genus of

plants in the Linnæan system.

JATROPHA CURCAS. The systematic name of a plant whose seeds resemble the castoroil seeds. See Ricinus mojor.

JATROPHYSICUS. (From 127gos, a physician, and ours, nature.) An epithet bestowed on some writings, which treat of physical subjects with relation to medi-

cines. JECORARIA. (From jecur, the liver; so named from its supposed efficacy in diseases of the liver.) See Hepatica terrestris. Also a name given to a vein in the right hand, because it was usually opened in diseases of the liver.

JECORARIA VENA. The hepatic vein.

Jecun. The liver.

The Placenta is. JECUR UTERINUM. by some, thus called, from the supposed similitude of its office with that of the

JEJUNUM. (From jejunus, empty.) Jejunum intestinum. The second portion of the small intestines, so called because it is

mostly found empty. See Intestines.

JELLY. Modern chymists have given this name to the mucilaginous substance, very soluble in water, and not at all in spirits of wine, that is obtained from all the soft and white parts of animals, such as the membranes, tendons, aponcuroses, cartilages, ligaments, and skin, by boung them in water. If the decoction or jelly be strongly evaporated, it affords a dry, brittle, transparent substance, known by the name of glue.

Jerusalem corvslips. See Pulmonaria ma-

Jerusalem oak. See Botrys vulgaris.

Jerusalem sage. See Pulmonaria macu-

Jessamine. See Jasminum.

JESUITANUS CORTEX. (Jesuitanus; from jesuita, a jesuit.) A name of the Peruvian bark, because it was first introduced into Europe by Father de Lugo, a jesuit. Cinchona.

JESUITICUS CORTEX. See Cinchona.

Jesuits bark. See Cinchona.

Jesustanus. (From jesuita, a jesuit.)

A trivial name of the Pernyian bark, because it was first introduced in Europe by

Father de Lugo, a jesuit.

JET. A black bitumen, hard and compact, like certain stones, found in great abundance in various parts of France, Sweden, Germany, and Ireland. It is brilliant and vitreous in its fracture, and capable of taking a good polish by friction: it attracts light substances, and appears to be electric, like amber; hence it has been called black amber; it has no smell, but when heated it acquires one like bitumen judaicum.

Jews pitch. See Bitumen judaicum. John's wort. See Huperieum.

JONTHI. See Ionthus.

Judicatorius. (From judico, to discern.) An obsolete term applied to a synocha of four days, because its termination

may certainly be foreseen.

JUGALE OS. (Jugalis; from jugum, a yoke; from its resemblance, or because it is articulated to the bone of the upper jaw, like a yoke.) Os mal.e. Os zugomatieum. The ossa malarum are the promient square bones which form the upper part of the cheeks. They are situated close under the eyes, and make part of the orbits. Each of these bones has three surfaces to be considered. One of these is exterior and somewhat convex. second is superior and concave, serving to form the lower and lateral parts of the orbit. The third, which is posterior, is very unequal and concave, for the lodgment of the lower part of the temporal muscle. Each of these bones may be described as having four processes, formed by their four angles. Two of these may be called orbitar pro-The superior one is connected cesses. with the orbitar process of the os frontis; and the inferior one with the malar process of the maxillary bone. The third is connected with the temporal process of the sphenoid bone; and the fourth forms a bony arch, by its connection with the zygomatic process of the temporal bone. In infants, these bones are entire and completely ossi-

JUGLANS. (Quasi Jovis glans, the royal fruit, from its magnitude.) 1. The name of a genus of plants in the Linnæan system. Class, Monoceia. Order, Polyandria. The walnut-tree.

2. The pharmacopogial name of the wal-The tree which bears this fruit is the Juglans regia of Linnaus :- foliolis ovlaibus glabris subserratis subsequalibus. It is a native of Persia, but cultivated in this coun-The unripe fruit, which has an astringent bitterish taste, and has been long employed as a pickle, is the part directed for medicinal use by the London College, on account of its anthelm ntic virtues. An extract of the green fruit is the most conve- obstructions, scorbut c affections, and some

sufficient length of time, and made agreeable to the stomach of the patient, by mixing it with cinnamon water.

Juglans Regia. The systematic name

of the walnut tree. See Juglans.

JUGULAR' VEINS. (Venæ jugularis; from jugulum, the throat.) These veins run from the head down the sides of the neck, and are divded, from their situation, into external and internal. The external or superficial, jugular vein receives the blood from the frontal, angular, temporal, auricular, sublingual or ranine, and the occipital veins. The internal, or deepseated, jugular vein, receives the blood from the lateral sinusses of the dura mater, the laryngeal and pharyngeal veins. jugulars unite, and form, with the subclavian vein, the superior vena cava, which terminates in the superior part of the right auricle of the heart.

JUGULUM. (From jugum, a yoke; because the yoke is fastened to this part.) The throat, or anterior part of the neck.

Jujubes. See Jujuba.

J. jubes. Jujubæ. (Arab.) A halfdried fruit of the plumb kind, about the size and shape of an olive, the produce of the Rhammes zizyphus of Linnæus. Jujubes, when in perfection, have an agrecable sweet taste, and in the southern parts of Europe, where they are common, they make an article of food in their recent state, and of medicine when half dried.

July flowers. See Caryophyllus ruber. Juneus odoratus. Fanum camelorum. Juneus aromatiens. Camel-hay. Sweet rush. This dried plant, Andropogon schænanthus of Linnæus, is imported into this country from Turkey and Arabia. It has an agreeable smell, and a warm, bitterish, not unpleasant taste. It was formerly employed as a stomachic and deobstruent.

Juniper. See Juniperus. Juniper gum. See Sandarack.

JUNIPERUS. (Juniperus; from juvenis, young, and pario, to bring forth; so called because it produces its young berries while the old ones are ripening.) 1. The name of a genus of plants in the Linnxan system. Class, Dioecia. Order, Monadelphia.

2. The pharmacopæial name of the common jumper, Juniperus communis of Linnaus: foliis ternis patentibus mueronatis, baeeis longioribus. Both the tops and berries of this indigenous plant are directed in our pharmacopæias, but the latter are usually preferred, and are brought chiefly from Holland and Italy. Of their efficacy as a stomachic, carminative, diaphoretic, and diuretic, there are several relations b physicians of great authority: and medical writers have also spoken of the utility of the juniper in nephritic cases, uterine nient preparation, as it may be kept for a cutaneous diseases. Our pharmacopoxias

direct the essential oil, and a spirituous distillation of the berries, to be kept in the shops. JUNIPERUS COMMUNIS. The systematic

name of the jumper-tree. See Juniperus.

JUNIPERUS LICIA. The systematic name of the plant which affords the frankincence. Sce Olibanum.

JUNIPERUS SABINA, The systematic name of the savine-tree. See Sabina.

JUPITER. The ancient chymical name of tin, because supposed under the government of that planet.

JUVANTIA. (From juvo, to assist.) Medicines, or assistances of any kind, which

relieve a distemper.

JUXTANGINA. (From juxtu, near, and angina, a quinsy.) A disease resembling a auinsy.

## K.

The systematic EMPERIA ROTUNDA. name of the plant which affords the officinal zedoary. Zedoria.

KAJEPUT OLEUM. See Cajeput oil. Kall. (Arab.) The Kali of the phar-"macopæias is the vegetable alkali or potasli. See Potassa.

KALI ACETATUM. See Acetas potassæ. KALI ENATUM. See Carbonas potassæ.

KALI ARSENICATUM A prepartion of arsenic, composed of the vegetable alkali and the oxyd of arsenic. It is the active ingredient in Fowler's mineral solution. See Liquor arseniculis.

KALI CITRATUM. Alkuli volutile, succo citri saturatum. The neutral saline liquor, a citrat of potash, is made by saturated prepared kali with lemon juice. It is the base of the saline draught; it possesses nervine and sudorific properties; and is exhibited in rheumatism, catarrh, and most febrile diseases,

KALI PREPARATUM. See Subcarbonas potassie.

KALI PURUM. See Potassa fusa.

KALI SULPHURATUM. See Sulphuretum

KALI TARTARIZATUM. Sce Turtras po-

KALI VITRIOLATUM. See Sulphas potassæ.

KEIRI. See Chieri.

The mineral alkali which is obtained in this country by burning marine

Kenato Pharyngæus. (From negas, a horn, and φαςυγέ, the pharynx.) A muscle so named from its shape, and insertion in the

pharenx.

KERMES. (Chermah, Arab.) Gramm Coccus baphica. Round redtinctovium. dish grains, about the size of peas, found in Spain, Italy, and the south of France, adhering to the branches of the scarlet oak. They are the nidus of a minute red animalcule, called Coccus quercus ilicis of Linnæ. The confectio alkermes, now obsoletc, was prepared with these, which possess corroborant and adstringent virtues.

Kermes mineralis. A preparation of antimony, so termed from its resemblance to the insect of that name. It is now disused in medicine, and gives place to the other preparations of antimony. Sec IIydrosulphuretum stibii rubrum.

Kernel wort. Scrophularia vulguris. KERVA. Kervah, Arab.) The ricinus. KETCHUP. The prepared liquor of the

mushroom. KEYSER'S PILLS. A once celebrated mercurial medicine, the method of preparing which was purchased by the French government, and has since been published by M. Richard. The hydrargyrus acetatus is considered as an adequate substitute for the more elaborate form of Keyser, M. Richard concludes his account of Keyser's pills with observing, that he considers it to be, without exception, the most effectual remedy for the venereal disease hitherto discovered. But further trials of this remedy do not justify the sanguine account; of its properties; though it may succeed when some of the other mercurial preparations have failed.

KIBES. A name for chilblains.

KIDNEYS. Renes. Two abdominal viscera, shaped like a kidney-bean, that secrete the urine. They are situated on each lumbar region, near the first lumbar vertebra, behind the peritoneum, and are composed of three substances, a cortical, which is the external, and very vascular; a tubulose, which consists of small tubes; and a papillous substance, which is the innermost. The kidneys are generally surrounded with more or less adipose membrane, and they have also a proper membrane, membrana propria, which is closely The accreted to the cortical substance. renal arteries, called also emulgents, proceed from the aorta. The veins evacuate their blood into the ascending cava. The absorbents accompany the blood-vessels, and terminate in the thoracic duct. nerves of the kidneys are branches of the eighth pair and great intercostals. The

excretory duct of this viscus is called the ureter. At the middle or pelvis of the kidney, where the blood-vessels enter it, is a large membranous bag, which diminishes like a finnel, and forms a long caual, or ureter, that conveys the urine from the kidney to the bladder, which it perforates obliquely.

KKEKUNEMALO. A pure resin, very similar to copal, but of a more beautiful whiteness and transparency. It is brought from America, where it is said to be used medicinally in the cure of hysterica, tetanus, &c. It forms the most beautiful of all

Varnishes

KIRI. (Kike, Arabian.) See Ricinus. KINA KINA. See Cinchona. KINKINA. See Cinchona.

KINO. (Indian.) Gummi gambiense.

Gummi rubrum adstringens gambiense. The tree from which this rean is a bined, though not botanically ascertained, is known to grow on the banks of the river Gambia, in Africa. On wounding its bark, the fluid kino immediately issues drop by drop, and, by the heat of the sun, is formed into hard masses. It is very like the resin called Sanguis draconis; is much redder, more firm, resinous, and adstringent, than catechu. It is now in common use, and is the most efficacious vegetable adstringent, or styptic, in the materia medica. Its dose is from twenty to thirty grains.

Knee-holly. See Ruscus. Knee pan See Patella.

Korro. (Polonese.) The plica polonica, or plaited hair.

KYNACHE. See Cynanche.

## L.

LABIA LEPORINA. (Leporina; from lepus, a hare, resembling a hare.) The hare-

fus, a hare, reser

LABORATORIUM. (From laboro, to labour.) A place properly fitted up for the performance of chym cal operations.

LABYRINTH. That part of the internal ear behind the cavity of the tympanum; it is constituted by the cochlea, vestibulum, and semicircular canals.

LAC. See Lacca.

LAC AMMONIACI. See Mistura ammo-

LAC AMYGDALE. A very pleasant, cooling, demulcent drink, calculated to allevate ardor urine, and relieve strangury. It forms a pleasant ptisan in coughs, housenesses, and catarrhs. See Mistura anygdale.

LAC ASSAFIETIDA. See Mistura ussafa-tida.

LAC SULPHURIS. See Sulphur præcipitatum. LACCA. (From lakah, Arab.) Gummi Lacca. Stick-lac. Gum lac. Serd-lac. Shell lac. The improper name of gum-lac is given to a concrete brittle substance, of a dark red colour, brought from the East Indies, incrustated on the twigs of the Cro ton lacciferum of Linnaus:-foliis ovatis tomentosis serrulatis petiolatis, colycibus to-mentosis, where it is deposited by a small insect, at present not scientifically known. It is found in very great quantities on the uncultivated mountains on both sides the Ganges; and is of great use to the natives in various works of art, as varnish, painting, dyeing, &c. When the resinous matter is broken off the wood into small pieces

of grains, it is termed seed-lac, and when melted and formed into flat plates, shell-lac. This substance is chiefly employed for making sealing-wax. A tincture of it is recommended as an antiscorbutic to wash the gums

LACHRYMA ABIEGNAS. See Terebinthina

argentarotensis.

LACHRY M.E. The tears. A limpid fluid secre ed by the lachrymal gland, and flowing on the surface of the eye.

LACHRYMAL BONE. See Unguis os. LACHRYMAL DUCTS. Ductus lach-rymales. The excretory ducts of the achrymal gland, which open upon the internal

surface of the upper ey. lid.

LACHRYMAL GLAND. Glandula lachrymalis. A glomerate gland, situated above
the external angle of the orbit, to a peculiar
depression of the frontal bone. It ecretes
the tears, and conveys them to the eye by
its excretory ducts, which are six or eight

in number.

LACHRYMAL NERVE. The fifth pair of nerves from the head is divided into several branches, the first of which is called the orbitary branch; this is divided into three more, the third of which is called the luchrymal branch; it goes off chiefly to the lachrymar gland.

LACONICUM. (Because they were much used by the people of Laconia.) A stove,

or sweating-room.

LACTATION. (From lacteo, to suckle.)

The giving suck.

LACTATS (Lactas.) Salts formed by the union of the acid of sour whey, or becic acid, with different bases; thus aluminous lactat, ammoniacal lactat, &c.

SI

LACTEALS. Vasu lactea. The absorbents of the mesentery, which originate in the small intestines, and convey the chyle from thence to the thoracic duct. They are very tender and transparent vessels, possessed of an infinite number of valves, which, when distended with chyle, a milky or lacteal fluid, give them a knotty appearance. They arise from the internal surface of the villous coat of the small intestines, perforate the other coats, and form a kind of net-work, whilst the greater num-ber unite one with another between the muscular and external coats. From thence they proceed between the laminæ of the mesentery to the conglobate glands. In their course they constitute the greater part of the gland through which they pass, being distributed through them several times, and curled in various directions. The lacteals, having passed these glands, go to others, and at length seek those nearest the mesentery. From these glands, which are only four or five, or perhaps more, the lacteals pass out and ascend with the mesenteric artery, and unite with the lymphatics of the lower extremities, and those of the abdominal viscera, and then form a common trunk, the thoracic duct, which, in some subjects, is dilated at its origin, forming the receptaculum chyli. See Nutri-

LACTIC ACID. (From lac, milk.) The

acid of sour milk.

Lactica. The Arabian name for that species of fever which the Greeks call Typhos, or Typhodes.

LACTIFUGA (From lac, milk, and fugo, to drive away.) Medicines which dispel

milk.

LACTUCA. (From lac, milk; named from the milk; juice which exudes upon its being wounded.) 1. The name of a genus of plants in the Linnzan system. Class, Syngenesia. Order, Polygamia aquales.

2. The pharmacopæial name of the garden-lettuce, the Lactuca sativa cultivated; it is esteemed as an wholsome aperient bitter anodyne, easy of digestion, but afford ing no nutriment. Lettuces appear to agree better with hot, bilious, melancholic temperaments, than the p'egma ic. The seeds possess a quantity of oily substance, which, triturated with water, forms an emulsion esteemed by some in ardor urinæ, and some diseases of the urinary passage. Lettuce was famous for the cure of the Emperor Augustus, and formed the opiate of Galen, in his old age; a proof that, in the warmer climates, it must acquire an exaltation of its virtues above what is met with in this country.

LACTUCA GRAVEOLEMS. Opium scented lettuce. Strong-scented lettuce. Lacuca sylvestris. Lactuca virosa of Linoans:—foliis horizontalibus carino aculeutes lentatis. A common plant in our hedges and

ditches. It has a strong ungrateful smell, resembling that of opium, and a bitterish acrid taste: it abounds with a milky juice, in which its sensible qualities seem to reside, and which appears to have been noticed by Dioscorides, who describes the odour and taste of the juice as nearly agreeing with that of the white poppy. Its effects are also said, according to Haller, to be powerfully narcotic. Dr. Collin, at Vienna, first brought the lactuca virosa into medical repute, and its character has lately induced the College of Physicians at Edinburgh to insert it in the catalogue of the Materia Medica. More than twentyfour cases of dropsy are said, by Collin, to have been successfully treated, by employing an extract prepared from the expressed juice of this plant, which is stated not only to be powerfully diuretic, but, by attenuating the viscid humours, to promote all the secretions, and to remove visceral obstructions. In the more simple cases, proceeding from debility, the extract, in doses of eighteen to thirty grains a-day, proved sufficient to accomplish a cure: but when the disease was inveterate, and accompanied with visceral obstructions, the quantity of extract was increased to three drachms; nor did larger doses, though they excited nausea, ever produce any other bad effect; and the patients continued so strong under the use of this remedy, that it was seldom necessary to employ any tonic medicines. Though Dr. Collin began his experiments with the lactuca at the Pazman hospital, at the time he was trying the arnica, 1771, yet very few physicians, even at Vienna, have since adopted the use of this plant. Plenc1z, indeed, has published a solitary instance of its efficacy, while Quarin informs us that he never experienced any good effect from its use; alleging, that those who were desirous of supporting its character, mixed with it a quantity of extractum Under these circumstances we scillæ, shall only say, that the recommendation of this medicine by Dr. Collin, will be scarcely thought sufficient to establish its use in England.

LACTUCA SATIVA. The systematic name

of the lettuce. See Lactuca.

Lactuca sylvestris. Scariola. The officinal name of the Lactuca scariola of Linnuis, which possesses a stronger degree of bitterness than the Lactuca sativa, and said to be more aperient and laxative. It is nearly similar, in virtue as in taste, to endive unclanched.

LACTUCA VIROSA The systematic name of 'be opium-scented lettuce. See Lactuca graveolens.

LACTUCELLA. (Deminutive of lactuca, the lettuce; so named from its milky juice.) The sow-thistle.

LACTUCIMINA. (From lacteo, to suckle;

so called because they happen chiefly to children while at the breast.) Aphthæ, or little ulcers, or crusty scabs, on the skin.

LACTUMEN. (From lac, milk; so named because it is covered with a white crust.) The achor, or scald-head; also a little crusty scab on the skin, affecting chiefly children at the breast.

LACUNE. (Lacuna; from lacus, a channel.) The mouths or openings of the exerctory ducts of muciparous glands in

the urethra, and other parts.

LADANUM. (From ladon, Arab.)

Labdanum. This resinous juice exudes upon the leaves of the Cistus cretiens of Linuxus :- aborescens exupulatus, foliis spatulato ovatis petiolatis enervies scabris, calycinis lanceolatis; in Candia, where inhabitants collect it by lightly rubbing the leaves with leather, and afterwards scraping it off, and forming it into irregular masses for exportation. Three sorts of ladanum have been described by authors, but only two are to be met with in the shops. The best, which is very rare, is in dark-coloured masses, of the consistence of a soft plaster, and growing still softer on being handled; the other is in long rolls, coiled up much harder than the preceding, and not so dark. The first has commonly a small, and the last a large, admixture of fine sand, without which they cannot be collected pure, independently of designed abuses: the dust blown on the plant by winds, from the loose sands among which it grows, being retained by the tenacious juice. The soft kind has an agreeable smell, and a lightly pungent bitterish taste: the hard is much weaker. Ladanum was formerly much employed internally as a pectoral and adstrugent in catarrhal affections, dysenteries, and several other diseases; at present, however, it is wholly confined to external use, and is an ingredient in the stomachic plaster, emplastrum ladani.

Ludies bedstraw. See Galium luteum. Ladies mantle. See Alchemilla. Ladies smock. See Cardamine.

LETIFICANTIA. (From latifico, to make glad.) This term liath been applied to many compositions under the intention of corduls; but both the medicine and distinction are now quite disused.

(Azyzecc, lax; so named parative laxity.) The right LAGAROS. from its comparative laxity.)

ventricle of the heart.

LAGOPHTHALMIA. (From hayes, a hare, and οφθαλμος, an eye; because it is believed that hares sleep with their eyes open.) Logophthalmos. The hare's eye. A disease in which the eye cannot be shut. The following complaints may arise from it: a constant weeping of the organ, in consequence of the interruption of the alternate closure and opening of the eyelids which motions so materially contri-

tribute to propelling the tears into the nose; blindness in a strong light, in consequence of the inability to moderate the rays which fall on the eye; on the same account, the sight becomes gradually very much weakened; incapacity to sleep where there is any light; irritation, pain, and redness of the eye, from this organ being exposed to the extraneous substances in the atmosphere, without the evelids having the power of washing them away in the natural man-

An enlargement or protrusion of the whole eye, or a staphyloma, may obviously produce lagophthalmos. But affections of the upper eyelids are the common causes. Heister says he has seen the complaint originate from a disease of the lower one. Now and then tagophthalmos depends on paralysis of the orbicularis muscle. A cicatrix, after a wound, ulcer, or burn, is the most frequent cause.

LAGOPODIUM. (From Augos, a hare, and mes, a foot; so called because it has narrow harry leaves, like the foot of a hare.) The herb hare's foot trefoil.

LOGOSTOMA. (From λαγος, a hare, and 50μα, the mouth; so called because the upper lip is divided in the middle like that of a hare.) The hare lip.

Lakeweed. See Hydropiper.

LAMAC. Gum-arabic

LAMBDACIMUS. A defect in speech, which consists in an inability to pronounce certain consonants, or is that stammering, or difficulty of speech, called Psellismus Lallans, that is, when the letter L is pronounced too liquid, and often in the place of R.

LAMBDOIDAL SUTURE. (Satura Lambdoidalis; from A, and usos, resemblance; because it is shaped like the leter A ) Occipital suture. The suture that unites the occipital bone to the two parietal bones.

LAMBITIVUM. (From lambo, to lick up.) A linctus or medicine to be licked up.

LAMELLA. (Dim. of lamina, a plate of The thin plates, or gills, of a metal.) mushroom.

LAMINA. (From Exace, to beat off.) A bone, or membrane, or any substance resembling a thin plate of metal. The lap of the ear.

LAMIUM ALBUM. (From Lamium, a mountain of Ionia, where it grew, or from lama, a ditch, because it usually grows about ditches and neglected places.) Urtica mortua. Galeopsis. Archangelica. Dead nettle. White archangel nettle. Uterine hæmorrhages and fluor lbus are s id to be relieved by infusions of this plant, from whose sensible qualities very little benefit can be expected.

LAMPSANA. See Lapsana.

LANCETTA. (Dim. of lancea, a spear.) A lancet. An instrument used in phleho-

LAONICA CORATIO. A method of curing the wort, by ev porating the morbid matter y topical applications.

LAPACTICA. (From AZTZZw, to evacu-

ate.) Purgative medicines.

LAPARA. From (λαπαζω, to empty; so named from its concave and empty appearance.) The flank.

LAPAROCELE (From Auraga, the flank, and xnan, a rupture.) A rupture through

the side of the belly.

(From λαπαζω, to evacu-LAPATHUM. ate; so named because it purges gently.) The dock.

LAPATHUM ACETOSUM. Se: Acetosa.

LAPATHUM ACUTUM See Oxylapathum. LAPATHUM AQUATICUM. See Hydrolupa-

LAPIDES CANCRORUM. See Cancer.

LAPIDELLUM. Lapidellus. (From lapis, a stone.) The name of a kind of spoon, form-rly used to take out small stones and fragments from the bladder.

LAPILLI CANCRORUM. Crab's stones. commonly called crab's eyes. See Cuncer.

LAPIS BEZOAR, See Bezoar.

LAPIS CERULEUS. See Lapis lazuli. CALAMINARIS. See Calamine. Hard carbonate of LAPIS CALCAREUS. lime.

LAPIS CYANUS. See Lapis lazuli

LAPIS HEMATITES. Se Hamatites.

LAPIS HIBERNICUS. Tegula hybernica. Ardesia hibernica Hardesia. Irish slate. A kind of slate, or very hard stone, found in different parts of Ireland, in a mass of a blueish black colour, which stains the hands. When dried and powdered, it is pale, or of a whitish blue, and by keeping grows black. In the fire it yields a sulphureous gaz, and acquires a pale red colour, with additional hardness. It is occasionally powdered by the common people, and taken in spruce beer, against inward

LAPIS HYSTRICIS. See Bezoar porcinum. LAPIS INFERNALIS. An old name for the

caustic potasli. See Potassa fusa.

LAPIS LAZULI. Lapis cyanus. A combination of silex, the blue finate of lime and sulphat of lime, and iron. This singular mixture forms a stone, of a beautiful opake blue, which it preserves in a strong heat, and does not suffer any alteration by the contact of air. It was formerly exhibited as a purgative and vomit, and given in epilepsy.

LAPIS MALACENSIS. See Bezoar porci-

LAPIS PORCINUS, See Bezoar porci-

LAPIS SIMIÆ. See Bezoar simiæ. LAPPA MAJOR. See Bardada.

LAPSANA. (Aadavn, from Lampsacus, the town near which it flourished; or from λαπαζω, to evacuate; because it was said

to relax the bowels.) Lampsana. Napium. Papillaris herba. Dock-cresses. Nipplewort. This plant, Lapsana communis of Linnaus, is a lacte-cent bitter, and nearly similar in virtues to the cichory, dandelion. and endive. It has been employed chiefly for external purposes, against wounds and ulcerations, whence the name of nipple-wort and papillaris

LAQUEUS GUTTURIS. A malignant inflammation of the tonsils, in which the patient appears as if he were suffocated with a

noose,

LARRASON. Antimonv.

Larch-tree. See Terebinthina veneta.

LARD. The English name of hog's fat, when melved down. Hog's lard, adeps suella, forms the base of many unguents, and is often eaten by the poor instead of

LARYNGOTOMY. (From xaevas, the larynx. and τεμνω, to cut.) See Bronchotomy.

LARYNX. (Azeuré, a Greek primitive.) A cartilaginous cavi y, situated behind the tongue, in the anterior part of the fauces, and lined with an exquisitely sensible membrane. It is composed of the annular or cricoid cartilage, the scutiform or thyroid, the epiglottis, and two arytenoid cartilages. The superior opening of the larynx is called the glottis The laryngeal arteries are branches of the external carouds. The laryngeal veins evacuate their blood into the external jugulars. The nerves of the larynx are from the eighth pair. The use of the larynx is to constitute the organ of voice, and to serve also for respiration.

Lascivus. (From lacio, 10 ensnare; upon account of its irregular motions.) An epithet used by Paracelsus for the chorea

Sanc'i viti.

LASER. (A term used by the Cyrenians.) The herb lasser-wort, or assafortida.

LASERPITIUM LATIFOLIUM. (From laser, perhaps from lazar, Arab ) The systematic name of the white gentian. See Gentiana

LASERPITIUM SILER. The systematic name of the heart wort. See Seseli,

LATERAL OPERATION. One mode of cutting for the stone is so called.

LATERAL SINUSSES The bifurcation and continua ion of the longitudinal sinus of the dura mater. They commence about the middle of the tentorium, one passing along each horizontal crucial spine within the tentorium, and round to the foramen lacerum in basi cranii, where the internal jugular vem begins. Their use is to carry the blood from the vein into the internal jugulars, which return it to the heart.

LATEX. (Latez, quod in venis terra lateat.) Water, or juice A term sometimes applied to the blood, as being the spring or source of all the humours.

LATERITIOUS SEDIMENT. (I.a.

429

teriteus; from later, a brick.) A term applied to the brick-like sediment occasionally deposited in the urine of people afflicted

LATHYRIS. (From Azba, to forget; because it was thought to affect the memory.)

LATHYRUS. (From Az 9w, to lie hid; so called from its diminutive size.) The vetch. LATINULUM. (From lateo, to lie hid.) The fomes, or hidden matter of infectious

LATISSIMUS COLLI. See Platysma myoides

LATISSIMUS DORSI. (Latissimus, sc. muscuius.; Antiscalptor of Cowper. Dorsi-lumbo sacro humeral of Dumas A muscle of the humerus, situated on the posterior part a of the trunk. It is a very broad, thin, and for the most part fleshy muscle, which is placed immediately under the skin, exccpt where it is covered by the lower extremity of the trapezius. It arises tendinous from the posterior half of the upper edge of the spine of the os ilium, from the spinous processes of the os sacrum and lumbar vertebræ, and from five or six, and sometimes from seven, and even eight, of the lowermost ones of the back; also tendinous and fleshy from the upper edges and external surface of the four inferior false ribs near their cartilages, by as many distinct slips. From these different origins the fibres of the muscle run in different direct ons; those from the ilium and false ribs run almost perpendicularly upwards; those from the sacrum and lumbar vertebræ, obliquely upwards and forwards; and those from the vertebræ of the back, transversely outwards and forwards, over the inferior angle of the scapula, where they receive a small thin bundle of fleshy fibres, which arise tendinous from that angle, and are inserted with the rest of the muscle, by a strong, flat, and thin tendon, of about two inches in length, into the fore-part of the posterior edge of the groove observed between the two tuberosities of the os humeri, for lodging the tendon of the long head of the biceps. In dissection, therefore, this muscle ought not to be followed to its insertion, till some of the other muscles of the os humeri have been first Its use is to pull the os humeri downwards and backwards, and to turn it upon its axis. Riolanus, from its use on certain occasions, gave it the name of anitersor. When we raise ourselves upon our hends, as in rising from off an arm-chair, we may easily perceive the contraction of this muscle. A bursa mucosa is found between the tendon of this muscle and the os humeri, into which it is inserted.

LAUCANIA. (From Azua, to receive; so called because it receives and conveys food.) The expliagus of the throat.

Laudanum. (From laus, praise; so

named from its valuable properties.) See Tinctura opi:

Laurel, cherry See Laurocerasus. Laurel, spurge. See Laureola.

LAUREOLA. (Dim. of laurus, the laurel, named from it resemblance to the laurel. Spurge laurel. The bark of this plant, Daphne laureola of Linnæus, is recommended to excite a discharge from the skin, in the same way as that of the thyme-

LAURO CERASUS. (From laurus, the laurel, and cerasus, the cherry-tree; so called because it has leaves like the laurel.) Common or cherry laurel. Prunus laurocerasus of Linnaus: - floribus racemosis fohis sempervirentibue dorso biglandulosis. The leaves of the lauro-cerasus have a bitter styptic taste, accompanied with a flavour resembling that of bitter-almonds, or other kernels of the drupacious fruits; the flowers also manifest a similar flavour. The powdered le ves, applied to the nostrils, excite sneezing, though not so strongly as tobacco. The kernel-like flavour which these leaves impair, being generally esteemed grateful, has sometimes caused them to be employed for culmary purposes, and especially in custards, puddings, blancmange, &c.; and as the proportion of this sapid matter of the lent to the quantity of the m lk is commonly inconsiderable, bad effects have seldom cusued. But as the poisonous quality of this laurel is now indubitably proved, the public ought to be cautioned against its internal use.

The following communication to the Royal Society, by Dr. Madden, of Dublin, contains the first and principal proofs of the deleterious effects of this vegetable upon mankind ;- "A very extraordinary accident that fell out here some months ago, has discovered to us a most dangerous poison, which was never before known to be so, though it has been in frequent use among us. The thing I mean is a simple water, distilled from the leaves of the lauro-cerasus; the water is at first milky, but the oil which comes over being, in a good measure, separated from the phlegm, by passing it through a flannel bag, becomes as clear as common water. It has the smell of bitter almonds, or peachkernel, and has been for many years in frequent use among our housewives and cooks, to give that agreeable flavour to their creams and puddings. It has also been much in use among our drinkers of drams; and the proportions they generally use it in has been one part of laurel Nor has this water to four of brandy. practice, however frequent, ever been attended with any apparent ill consequences, till some time in the month of Septem-ber 1728, when it happened that one Martha Boyse, a servant, who lived with a person who sold great quantities of

this water, got a bottle of it from her mistress, and gave it to her mother Ann Boyse made a present of it to Frances Eaton, her sister, who was a shopkerper in town, and who she thought might oblige her customers with it. Accordingly, in a few days, she gave about two ounces to a woman called Mary Whaley, who drank about two-thirds of what was filled out, and went away. Frances Eaton drank the rest. In a quarter of an hour after Mary Whaley had drank the water, (as I am informed,) she complained of a violent disorder in her stomach, soon after lost her speech, and died in about an hour, without vomiting, or purging, or any convulsion. The shopkeeper, F. Eaton, sent word to her sister, Ann Boyse, of what had happened, who came to her upon the message, and affirmed that it was not possible the cordial (as she called it) could have occa-sioned the death of the woman; and, to convince her of it, she filled out about three ounces and drank it. She continued talking with F. Eaton about two minutes longer, and was so earnest to persuade her of the liquor's being inoffensive, that she drank about two spoonfuls more, but was hardly well seated in her chair when she died without the least groan, or convulsion. Frances Eaton, who, as before observed, had drank somewhat more than a spoonful, found no disorder in her stomach, or elsewhere; but, to prevent any ill consequences, she took a vomit immediately, and has been well ever since."-Dr. Madden mentions another case, of a gentleman at Kilkenny who mistook a bottle of laurelwater for a bottle of ptisan. What quantity he drank is uncertain, but he died in a few minutes, complaining of a violent disorder in the stomach. In addition to this, we may refer to the unfortunate case of Sir Theodosius Boughton, whose death, in 1780, an English jury declared to be occasioned by this poison. In this case, the active principle of the lauro-cerasus was concentrated by repeated distillations, and given to the quantity of one ounce; the suddenly fatal effects of which must be still in the recollection of the public. brute animals this poison is almost instantaneously mortal, as amply appears by the experiments of Madden, Mortimer, Nicholls, Fontana, Langrish, Vater, and others. The experiments conducted by these gentlemen shew, that the laurel-water is destructive to animal life, not only when taken into the stomach, but also on being injected into the intestines, or applied externally to different organs of the body. It is remarked, by Abbé Fontana, that this poison, even "when applied in a very small quantity to the eyes, or to the inner part of the mouth, without touching the esophagus, or being carried into the stomach, is capable of killing an animal in afew

minutes: whilst, applied in a much greater quantity to wounds, it has so little activity, that the weakest animals, such as pigeons, resist its action."

The most volatile is the most active part of the lauro-cerasus; and if we judge from its sensible qualities, an analogous principle seems to pervade many other vegetable substances, especially the ker lels of drupaceous truits; and in various species of the amygdalus, this sapid principle extends to the flowers and leaves. It is of importance to notice, that this is much less powerful in its action upon human subjects than upon dogs, rabbits, pigeons, and reptiles. To poison man, the essential oil of the laurocerasus must be separated by distillation, as in the spirituous o common taurel-water; and unless this is strongly enibued with the oil, or given in a large dose, it proves inno-Dr. Cullen observes, that the sedative power of the lauro-cerasus acts upon the nervous system in a different manner from opium and other narcotic substances, whose primary action is upon the animal functions; for the lauro-cerasus does not occasion sleep, nor does it produce local inflammation, but seems to act directly upon the vital powers. Abbé Fontana supposes that this poison destroys animal life, by exerting its effects upon the blood; but the experiments and observations from which he draws this opinion are evidently inconclusive. It may also be remarked, that many of the Abbé's experiments contradict each other. Thus it appears, from the citation given above, that the poison of this vegetable, when applied to wounds, does not prove fatal; but future experiments led the Abbé to assert, that the oil of the lauro-cerasus, "whether given internally, or applied to the wounds of animals, is one of the most terrible and deadly poisons known." Though this vegetable seems to have escaped the notice of Stoerck, yet it is not without advocates for its medical use. Linnæus informs us, that in Switzerland it is commonly and successfully used in pulmonary complaints. Langrish mentions its efficacy in agues; and as Bergius found bitter almonds to have this effect, we may, by analogy, conclude that this power of the lauro-cerasus, is well established. Baylies found, that it possessed a remarkable power of diluting the blood, and, from experience, recommended it in all cases of disease supposed to proceed from too dense a state of that fluid; adducing particular instances of its efficacy in rheumatism, asthmas, and in schirrous affections. Nor does this author seem to have been much afraid of the deleterious quality of lauro-cerasus, as he directs a pound of its leaves to be macerated in a pint of water, of which he gives from thirty to sixty drops three or four times a-day.

LAUROSIS. The spodium of silver; so

called from Mount Laurus, where there were silver mines.

LAURUS. (From laus, praise; because it was usual to crown the heads of eminent men with branches of it.) 1. The name of a genus of plants in the Linnæan system. Class, Enneaudria. Order, Monogynia. The laurel.

2. The pharmacopæial name of the sweetbay. Laurus nobilis of Linnæus :- foliis venosis lanceolatis pereunantibus, floribus quadrifidis. This tree is a native of Italy, but cultivated in our gardens and shrubberies as a handsome evergreen. The teaves and berries possess the same medicinal qualities, both having a sweet fragrant smell, and an aromatic adstringent taste. The laurus of honorary memory, the distinguished favourite of Apollo, may be naturally supposed to have had no inconsiderable fame as a medicine; but its pliarmaceutical uses are so limited in the practice of the present day, that this dignified plant is now rarely employed, except in the way of enema, or as an external application; thus the leaves are directed in the decoctum pro fomento, and the berries in the emplastrum cumini.

LAURUS BENZOIN. The systematic name of the benjamin-tree. See Benzoi-

LAURUS CAMPHORA. The systematic name of the camphire-tree. See Camphora. LAURUS CINNAMOMUM, The systematic name of the cinnamon-tree. See Cinnamo mum

The systematic LAURUS CULILAWAN. name of the plant whose bark is called cortex culilawan in the shops.

LAURUS NOBILIS. The systematic name of the sweet-bay tree. See Laurus.

LAUNUS SASSAFIIAS. The systematic name of the sassafras-tree. See Sassafras.

Lavender, French. See Stachas.

LAVENDULA. (From lavo, to wash; so called, because, on account of its fragrancy, it was used in baths.) 1. The name of a genus of plants in the Linnæan system. Class, Didyuamia. Order, Gym-

2. The pharmacopoial name of the common lavender. Lavendula spica of Linnæus:-foliis sessilibus lanceolato linearibus margine revolutis, spica interrupta nuda. A native of the southern parts of Europe, but cultivated in our gardens on account of the fragrance of its flowers. Their taste is bitter, warm, and somewhat pungent; the leaves are weaker and less grateful. The essential oil, obtained by distillation, is of a bright yellow colour, of a very pungent taste, and possesses, if carefully distilled, the fragrance of the lavender in perfection. Lavender has been long recommended in nervous debilities, and various affections proceeding from a want of energy in the

animal functions. The College directs an essential oil, a simple sp rit, and a compound tincture, to be kept in the shops.

LAVENDULA SPICA. The systematic name of the common lavender. See Laven-

LAVENDULA STECHAS. The systematic name of the French lavender. See Stæ-

LAVER. (From lavo, to wash; so named because it is found in brooks, where it is constantly washed by the stream.) 1. The brook-lime.

2. The English name of a species of fucus which is eaten as a delicacy.

Lavipedium. (From lavo, to wash, and pes, the foot.) A bath for the feet.

Lawsonia inermis. The systematic

name of the true alkanna. See Alkanna

LAXATIVA. (From laxo, to loosen.) Gen-

tle purgatives.

LAXATOR TYMPANI. (From laxo, to loosen; so called from its office to r lax the drum of the ear.) Externus mallei of Albinus. Anterior mallei of Winslow. Obliquus auris of Douglas. Externus anvis vel laxator internus of Cowper, and Spheni salpingo mallien of Dumas. A muscle of the internal ear, that draws the malleus obliquely forwards towards its origin; consequently, the membrana tympani is made less concave, or is relaxed.

LAZULUS. (From azul, Arabian.) precious stone, of a blue colour. The lapis lazuli.

LEAD. Plumbum. A metal found in considerable quantity in many parts of the earth, in different states, seldom if at all in the metallic state. It is found in that of oxyd, red lead ore, mixed with a portion of iron, clay, and other earths. The colour of this ore is aurora red, resembling red arsenic. It is found in small lumps, of an indeterminate figure, and also crystallized in four-sided rhomboidal

Combined with carbonic acid, it forms the sparry lead ore, so called because it has the texture and crystallization of certain spars. There are a great many varieties of this kind. It is found united with sulphuric, phosphoric, arsenic, molybdic, and chromic acids. Lastly, lead is found mineralized by sulphur, forming what is called galena (sulphurct of lead,) which is by far its most abundant ore. This ore, which is very common, is found both in masses and crystals.

The primitive form of its crystals is a cube. Its colour is of a blueish lead grey. It has a considerable metallic lustre, its texture is foliated. It stains the fingers, and often feels greasy It contains in general a minute quantity of silver.

Properties of Lead.-Lead is of a blueish white colour when fresh cut. It is malle-

able. It soon tarnishes in the atmosphere. It may easily be cut with a knife, and stains the fingers blueish-grey when rubbed. It fuses at 550° Fahr, and renders other more refractory metals fusible. It becomes vitrified in a strong and continued heat, and vitrifies various other metals. It is the least clastic of all the metals. It is very lammable, but it possesses very little ductility. Its specific gravity is 11.435. crystallizes by cooling in small octahedra. When fused, its surface first becomes yellow and then red. It unites by fusion with phosphorus and sulphur. The greater part of the acids act upon it. The sulphuric acid requires the assistance of a boiling Ni ric acid is decomposed by it. Muriatic acid acts very weakly on it. Acetic acid dissolves it. Fluoric acid attacks it by heat, and slightly in the cold. It combines with other metals, but few of its alloys are applied to any use. combined with mercury it forms a crystallizable alloy, which becomes fluid when triturated with that of bismuth.

LEA

432

Method of obtaining Lead .- In order to obtain lead in a great way, the ore is picked from among the extraneous matter with which it was naturally mixed. It is then pulverized and washed. It is next roasted in a reverberatory furnace, in which it is to be agitated, in order to bring all its surfaces in contact with the air When the external parts begin to soften, or assume the form of a paste, it is covered with charcoal, the mixture is stirred, and the heat increased gradually; the lead then runs on all sides, and is collected at the bottom of the furnace, which is perforated so as to permit the metal to flow into a receptable defended by a lining of char-

coal.

The scoria remaining above in the furnace still retain a considerable proportion of lead; in order to extract it, the scoria must be fused in a blast furnace. The lead is by that means separated, and cast into iron moulds, each of which contains a portion called a pig of lead. These pigs are sold under the name of ore lead.

To disengage the silver from lead thus obtained, the metal is subjected to the action of the refining furnace. The continual application of a quantity of fresh air, which is thrown by means of large bellows upon the fused lead, which is at the same time heated as intensely as possible, oxydates the lead, and converts it into the yellow scaly oxyd, known by the name of litharge.

This scaly oxyd being driven off from the surface of the fused metal, as it is formed, leaves the silver alone unaltered at the bottom.

The lytharge is then to be fused in contact with charcoal, that it may assume the properties of metallic lead,

In order to obtain perfectly pure lead, the lead of commerce may be dissolved in pure nitric acid, and the solution be decomposed, by adding to it, gradually, a solution of sulphate of soda, so long as a precipitate ensues. This precipitate, which is sulphate of lead, must then be collected on a filter, washed repeatedly in distilled water, and then dried. In order to reduce it to its metallic state, let it be mixed with two or three times its weight of black flux, introduce the mixture into a crucible, and expose it briskly to a red heat.

Lead, when injudiciously administered. or taken accidentally nto the body, causes emaciation, violent colics, paralysis, tremors, and contractions of the limbs; and as they generally come on gradually, the cause is sometimes overlooked till it be too late. Poisoning from lead is never intentional, but only accidental; either from liquors becoming impregnated with lead, by being improperly kept in vessels lined or glazed with lead, or to which lead has been criminally added, to correct its acidity; or among manufacturers who work much with lead, as painters, or plumbers, and who are not sufficiently attentive to avoid swallowing it. The presence of lead in any suspected liquor is detected by the hydro-sulphuret of potash, which forms with it a brown precipi ate, not soluble in diluted muriatic acid, and still more certainly by evaporating a portion of the liquor to dryness, and exposing the extract to a heat sufficient to reduce the lead.

The preparations of lead used in medicine are :--

1. Oxidum plumbi album. See Cerussa and Plumbi carbonas.

2. Oxidum plumbi rubrum. See Minium,

3. Oxidum plumbi semivitreum. See Lithargyrum and Oxidum plumbi semivitreum.

4. Superacetas plumbi. See *Plumbi su*peracetas.

5 Liquor plumbi acetatis. See Liquor plumbi acetatis.

6. Liquor plumbi acetatis dilutus. See Liquor plumbi acetatis dilutus.

LAZULI LAPIS. See Lapis lazuli.

LEDUM PALUSTRE. The systematic name of the rosmarinus sylvestris. See Rosmarinus sylvestris.

LEENA. (From Acasta, a lioness; so named from its power.) A plaster for the

LEECH, Hirudo. A genus of insects belonging to the order of vermes intestina. The body moves either forward or backward. There are several species, principally distinguished by their colour; but that most known to medical men is the

hirudo medicinalis, or medicinal leech, which grows to the length of two or three

inches. The body is of a blackish brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and lines grow faint, and almost disappear, at some seasons. The head is smaller than the tail, which fixes itself very firm v to any thing the creature pleases. It is vaviatious, and produces but one young one t a time, which is in the month of July. It is an inhabitant of clear running waters, and is well known for its use in bleeding. The species most nearly approaching this, and which it is necessary to distinguish, is the hirudo sanguisuga, or horse leech. This is larger than the former; its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish green, it. ving a yellow laternal margin. It inhabits stagnant waters.

The leech's head is armed with a sharp instrument that makes three wounds at once. They are three sharp tubereles, strong enough to cut through the skin of a man, or even of an ox, or horse. The moath is, as it were, the body of the pump, and the tongue, or fleshy nipple, the sucker; by the working of this piece of mechanism, the blood is made to rise up to the conduit which conveys it to the animal' stomach, which is a membranaccous skin, divided into twenty-four small cells. The blood which is sucked out is there preserved for several months, almost without enagulating, and proves a store of provision to the animal. The nutritious parts, absorbed after digestion by animals, need not in this to be disengaged from the heterogeneous substances; nor indeed is there an anus discoverable in the leech; mere transpiration seems to be all that it performs, the matter fixing on the surface of the body, and afterwards coming oil in small threads. Of this, an experiment may be tried, by putting a leech into oil, where it keeps alive for several days; upon being taken out, and put into water, there appears to locsen from its body a kind of slough, shaped like the creature's body. The organ of respiration, though unascertained, seems to be situated in the mouth; for if, like an inseet, it drew breath through vent-holes, it would not subsist in oil, as, by it, these would be stopped up.

The first species only is used in medicine; being applied to the skin in order to draw off blood. With this view they are employed to bleed young children, and for the purposes of topical bleeding, in cases of inflammation, fulness, or pain. They may be employed in every case where topical bleedings are thought necessary, or where venesection cannot be performed. If the leech does not fasten, a drop of sugared milk is put on the spot it is wished to fix on, or a little blood is drawn by means of a slight puncture; after which

it immediately settles. The leech, when fixed, should be watched, lest it should find its way into the anus, when used for the hæmarchoids, or penetrate into the osophagus, if e nployed to draw the gums; otherwise it might fix upon the stomach, or intestines. In such a case, the best and quickest remedy is to swallow some salt: which is the method practised to make it loose its hold, when it sucks longer than is intended. Vegetable or volatile alkali, pepper, or acids, also make it leave the part on which it was applied. Cows and horses have been known to receive leeches, when drinking, into the throat; and the usual remedy is to force down some salt, which makes them fall off. If it is intended that the leech should draw a larger quantity of blood, the end of the tail is cut off; and it then sucks continually, to make up the loss it sustains. The discharge occasioned by the puncture of a leech is usually of more service than the process itself. When too abundant, it is easily stopped with brandy, vinegar, or other styptics, or with a compress of dry linen rags, bound strongly on the bleeding orifice. They are said to be very restless before a change of w ather, if confined to glasses, and to fix themselves above the water on the approach of a fine day.

As these little animals are depended on for the removal of very dangerous diseases, and as they often seem capriciously determined to resist the endeavours made to eause them to adhere, the following directions are added, by which their assistance may, with more certainty, be obtained.

The introducing a hand, to which any ill-flavoured medicine adheres, into the water in which they are kept, will be often sufficient to deprive them of life; the application of a small quantity of any saline matter to their skin immediately oc-casions the expulsion of the contents of their stomach; and what is most to our purpose, the least flavour of any medicament that has been applied remaining on the skin, or even the accumulation of the matter of perspiration, will prevent them from fastening. The skin should therefore, previous to their application, be very carefully cleansed from any foulness, and moistened with a little milk. The method of applying them is by retaining them to the skin by a small wine-glass, or the bottom of a large pill-box, when they will, in general, in a little time fasten themselves to the skin. On their removal, the rejection of the blood they have drawn may be obtained by the application of salt externally; but it is to be remarked, that a few grains of salt are sufficient for this purpose; and that covering them with it, as is sometimes done, generally destroys them.

LEEK. Allium porrum. A well-known vegetable, much employed for eulmary

purposes. The recent root and juice are exhibited internally in quartan fever, in dyspepsy, dropsy, asthma, and scurvy. See Porrum.

LEGNA. (From Asyrov, a fringed edge.) The extremities of the pudenda muliebruin.

LEGUMEN. (From lego, to gather; so called because they are usually gathered by the hand.) All kinds of pulse are so called.

LEICHEN. See Lichen.

LEIENTERIA. See Lienteria.

LEIPOPSYCHIA. (From Aure, to leave, and fuxn, the soul, or life.) A swoon. See Syncope.

(From λειπω, to leave, and LEIPOPYRIA. mue, heat.) A kind of ardent fever, where the internal parts are scorched with heat, while the external parts are cold.

LEIPOTHYMIA. (From λειτω, to leave, and Sυμος, the mind.) See Lipothymia.

LEME. (From λα, much, and μυω, to wink.) A defect in the eyes, when they are always winking.

LEMITHOCHORTON. See Corallina Corsi-

LEMMA. (From AETTW, to decorticate.) Bark. The skin.

LEMNIUS. (From Lemnos, whence it is brought.) A species of bole called terra lemnia, or earth of Lemnos.

Lemon. See Limon.

Lemon scurvy-grass. See Cochlearia hor-

LENIENTIA. (From lenio, to assuage.) Medicines which abate irritation.

LENITIVA. (From lenis, gentle.) Medicines which gently palliate diseases. Gen-

tle purgatives.

LENITIVE ELECTUARY. A preparation composed chiefly of senna and some aromatics, with the pulp of tamarinds. given in doses of a tea-spoonful, or more, frequently repeated, as a mild laxative; and, when fresh, it answers this purpose

well. See Confectio Sennæ.

LENS. (A lentore; from its glutinous quality.) 1. The lentil. \$\phi \text{220}\$ of the Greeks. Eroum lens of Linn\text{2015}:--fedunculis subbifloris; seminibus compressis, convexis. There are two varieties; the one with large, the other small seed. are eaten in many places as we eat peas. than which they are more flatulent, and more difficult to digest. A decoction of these seeds is used as a lotion to the ulcerations after small-pox, and, it is said, with success.

\* 2. See also Chrystalline lens.

LENTICULA. (Dim. of lens, a lentil.) A smaller sort of lentil. Also a freckle, or small pustule, resembling the seeds of lentil.

LENTICULAR. (From lenticulaire, doubly convex.) A surgical instrument, employed for removing the jagged particles of bone from the edge of the perforation made in the cranium with the trephine.

(From lenticula.) A LENTICULARIA. species of lentil.

LENTIGO. (From lens, a lentil; so named from its likeness to lentil-seeds.) A freckle.

LENTIL. An annual vegetable of the pulse kind, much used for improving the flavour of soups.

LENTISCUS. (From lentesco, to become clammy; so called from the gumminess of its juice.) The mastich-tree.

LENTOR. (From lentus, clammy.) A

viscidity or siziness of any fluid.

LEONINUS. (From leo, the lion.) epithet of that sort of leprosy called leontiasis.

LEONTIASIS. (From LEWF, a lion; so called because it is said lions are subject to it.) A species of leprosy resembling the elephantiasis.

LEONTODON. (From NEWV, the lion, and ofse, a tooth; so called from its supposed resemblance. The name of a genus of plants in the Linnzan system. Class, Syngenesia. Order, Polygamia aqualis. The dandelion.

LEONTOPODIUM. (From Asser a lion, and πες, a foot; so named from its supposed resemblance.) The herb lion's foot.

LEONURUS. (From AEW, a lion, and sga, a tail: so named from its likeness.) 1. The name of a genus of plants in the Linnæan system. Class, Didynamia. Order, Gymnospermia. Lion's tail.

2. The name, in some pharmacopæias,

for the lion's tail.

Leopard's bane. See Arnica.

LEPIDIUM. (From λεπις, a scale; so named from its supposed usefulness in cleansing the skin from scales and impurities.) Pepper-wort.

LEPIDOSARCOMA. (From heris, a scale, and oage, flesh.) An irregular scaly tu-

LEPISMA. (From λεπιζω, to decorticate.) Decortication. A perling off of the skin.

LEPRA. (From hearts, a scale; named from its appearance. The leprosy. A disease in the class cachexiae, and order impetigines, of Cullen. Dr. Willan describes this disease as characterized by scaly patches, of different sizes, but having always nearly a circular form. In this country, three varieties of the disease are observed, which he has described under the title of Lepra vulgaris, Lepra alphos, Lepra nigricans.

1. The Lepra vulgaris exhibits first small distinct elevations of the cuticle, which are reddish and shining, but never contain any fluid; these patches continue to enlarge gradually, till they nearly equal the dimensions of a crown-piece. They have always an orbicular, or oval form; are covered with dry scales, and surrounded by a red border. The scales accumulate on them. so as to form a thick prominent crust,

which is quickly re-produced, whether it fall off spontaneously, or may have been forcibly detached. This species of lepra sometimes appears first at the elbow, or on the fore-arm; but more generally about the In the latter case, the primary patch forms immediately below the patella, within a few weeks, several other scaly circles appear along the fore part of the leg and thigh, increasing by degrees, till they come nearly into contact. The disease is then often stationary for a considerable length of time. If it advance further, the progress is towards the hip and loins; afterwards, to the sides, back, shoulders, and, about the same time, to the arms and hands. In the greater number of cases, the hary scalp is the part last affected: although the circles formed on it remain for some time distinct, yet they finally unite, and cover the whole surface on which the hair grows with a white scaly incrustation. This appearance is attended, more especially in hot weather, with a troublesome itching, and with a tratery discharge for several hours, when any portion of the crust is detached, which takes place from very slight impressions. The pubes in adults is sometimes affected in the same manner as the head: and if the subject be a female, there is usually an internal pruritus pudendi. In some cases of the disorder, the nals, both of the fingers and toes, are thickened, and deeply in-dented longitudinally. When the lepra ex-tends universally, it becomes highly disgus ing in its appearance, and inconvenient from the stiffness and torpor occasioned by it in the limbs. The disease, however, even in this advanced stage, is seldom disposed to terminate spontaneously. It continues nearly in the same state for several years, or sometimes during the whole life of the person affected, not being apparently con-nected with any disorder of the constitution.

2. Lepra alphos. The scaly patches in the alphos are smaller than those of the lepra vulgaris, and also differ from them in having their central parts depressed or indented. This disorder usually begins about the elbow, with distinct, eminent asperities, of a dull red colour, and not much longer than papilla. These, in a short time, dilate to nearly the size of a silver penny. Two or three days afterwards, the central part of them suffers a depression, within which small white powdery scales may be observed. The surrounding border, however, still continues to be raised, but retains the same size and the same red colour as at first. The whole of the fore-arm, and sometimes the back of the hand, is spotted with similar patches: they seldom become confluent, excepting round the elbow, which, in that case, is covered with an uniform crust. This affection appears in the same manner upon the joint of the knee, but without spreading far along the thigh or leg. Dr. Willan has seldom seen it on the trunk of the body, and never on the face. It is a disease of long duration, and not less difficult to cure than the foregoing species of lepra; even when the scaly patches have been removed by persevering in the use of suitable applications, the cuticle still remains red, tender, and brittle, very slowly recovering its usual texture. The alphos, as above described, frequently occurs in this country.

3. The Lepra nigricans differs little from the lepra vulgaris, as to its form and distribution. The most striking difference is in the colour of the patches, which are dark and livid. They appear first on the legs and fore-arms, extending afterwards to the thighs, loins, neck, and irands. central part is not depressed, as in the alphos. They are somewhat smaller in size than the patches of the lepra vuigaris, and not only is the border livid or purplish, but the livid colour of the base likewise appears through the scaly incrustation, which is seldom very thick. It is further to be observed, that the scales are more easily detached than in the other forms of lepra, and that the surface remain longer excoriated, discharging lymph, often with an intermixture of blood, till a new incritstation forms, which is usually hard, brittle, and irregular. The lepra nigricans affects persons whose occupation is attended with much fatigue, and exposes them to cold or damp, and to a precarious or in oper mode of diet; as soldiers, brewers, labourers, butchers, stage-coachmen, scullermen, &c.; some women are also liable to it, who are habituated to poor living and constant

LEPRA GRECORUM. The lepra vulgaris, alphos, and nigricans, have all been so described.

Leprosy. See Lepra.

LEPTUNTICA. (From Aerros, thin.) At tenuating medicines.

LEFTYSMUS. (From Assatos, slender.) Attenuation, or the making a substance less solid.

LEROS. (From Augs, to trifle.) A slight delirum.

LETHARGY. Lethargus. A heavy and constant sleep, with scarce any intervals of waking; when awakened, the person answers, but ignorant or forgetful of what he said, immediately sinks into the same state of sleep. It is considered as an imperfect apoplexy, and is mostly symptomatic.

Lethea. (From ληθη, forgetfulness; so named because it causes forgetfulness.) The name of the poppy.

Lettuce, garden. See Lactuca.

LEUCACANTHA. (From ASUROS, white,

and axavea, a thorn; so named from its white blessom.) The cotton-thistle.

LEICANTHEMUN VULGARE, (From Nevxoc, white, and aronnos, a flower; so called from its white floret.) See Bellis major.

LECCELECTRUM. (From Asunos, White, and exertgor, amber.) White amber.

LEUCO. ACHANUM. (From ASURSS, white, and Auxarov, a herb; so named from its co-

lour.) Wild valerian.

LÉUCOMA. (From Acunoc, white.) Lencoma and albugo are often used synonymously, to denote a white opacity of the cornea. Both of them, according to Scarpa, are essentially different from the nebula of the cornea; for they are not the consequence of chronic ophthalmy, attended with varicose veins, and an effusion of a milky serum into the texture of the delicate continuation of the conjunction over the cornea; but are the result of violent acute opinthalmy. In this state, a dense coagulating lymph is extravasated from the arteries; sometimes superficially, at other times deeply into the substance of the cornea. On other occasions, the disease consists of a firm callous cicatrix on this membrane, the effects of an ulcer, or wound, with loss of substance. The term albugo strictly belongs to the first form of the disease: leucoma to the last, more particularly when the opacity, occupies the whole, or the chief part, of the cornea.

LEUCONYMPHEA. (From ASUROS, white, and rumpaia, the water-lily.) See Nymphica

LEUCOPHAGIUM. (From Neuros, White, and one, to eat.) A medicated white food.

LEUCOPHLEGMATIC. (Leucophlegmasia; from neuros, white, and prepua, phlegm.) A term applied by the older medical writers to a dropsical habit of

LEUCOPIPER. (From Asunos, white, and

TITTELE, pepper.) See Piper nigrum.

LEUCORRŒA. (From Asunoc, white, and pew, to flow.) Fluor albus. The whites. An increased secretion of white mucus from the vagina of women, arising from debility, and not from the venereal virus.

Lercornnois. (From Dauxos, white, and pio, to flow.) A discharge of mucus from

the intestines.

LEVATOR. (From levo, to lift up.) A muscle whose office is to lift up the part to

which it is actached.

LEVATOR ANGULI ORIS. Elevator labicium communis of Douglas. Caninus of Winslow, and Sas maxillo lubial of Dun.as. A muscle si uated above the mouth, which draws the corner of the mouth upwards, and makes that part of the cheek opposite to the clin prominent, as in smaling. It arises than and fleshy from the hotlow of the superior maxillary bone, between the oculi-

reot of the socket of the first grinder and the foramen infra orbitarium, and is inserted into the angle of the mouth and under lip, where it joins with its antagonist.

Levaryr magnus, LEVATOR ANL seu internus of Bouglas. Pubo coccigi annulare of Dumas. This muscle arises from the os pubis, within the peivis, as far up as the upper edge of the foramen thyroideum, and joining of the os pubis with the es ischum, rom the thin tendinous membrane that covers the obturator internus and coccygaus muscles, from the spinons process of the ischium. From these origins all round the inside of the pelvis, its fibres run down like rays from the circumference to a centre, to be inserted into the sphilleter ani, acceleratores urina, and anterior part of the two last bones of the os coccygis, surrounding the extremity of the rectum, neck of the bladder, prostate gland, and part of the vesicula seminales. Its fibres, joining with those of its fellow, form a funnel-shaped hote, that draws the rectum upwards after the evacuation of the faces, and assists in shinting it. The levatores am also sustain the contents of the pelvis, and assist in ejecting the semen, urine, and contents of the rectum, and perhaps, by pressing upon the veins, con-tribute greatly to the erection of the

LEVATOR LABII INFERIORIS. vator menti of Albinus. Incisivus inferior of Winslow. Elevator labii inferioris proprius of Douglas. A muscle of the mouth situated below the lips; it arises from the lower jaw, at the roots of the alveoli of two incisor teeth and the cuspidatus, and is inserted into the under lip and skin of the chin.

LEVATOR LABI SUPERIORIS AL-ÆQUE NASI. Elevator labii superioris proprius of Douglas Incisivus lateralis et Winslow. A muscle of pyramidalis of the mouth and lips, that raises the upper lip towards the orbit, and a little outwards; it serves also to draw the skin of the nose upwards and outwards, by which the nostril is dilated. It arises by two distinct origins; the first, broad and fleshy, from the external part of the orbitar process of the superior maxillary bone, immediately above the ioramen infra orbitarium; the second, from the nasal process of the superior maxillary bone, where it joins the os frontis. The first portion is inserted into the upper hip and orbicularis muscle, the second into the upper lip and outer part of the ala nasi.

LEVATOR LABII SUPERIORIS PRO-PalUS. Musculus incisivus. It arises under the edge of the orbit, and is inserted into the middle of the lip.

LEVATOR OCULI. See Rectus superior

Levator palati LEVATOR PALATI. mollis of Albirus. Petrosalpingo-stablilinus, vel salpingo-staphilinus internus vulgo of Winslow. Salpingo-staphilinus of Valsalva. Pterigo-staphilinus externus vulzo of Douglas. Spheno-staphilinus of Cowper. A Muscle situated between the lower jaw and the os hyoides laterally. It arises tendinous and fleshy from the extremity of the petrous portion of the temporal bone, where it is perforated by the Eustachian tube, and also from the membranous part of the same tube, and is inserted into the whole length of the velum pendulum palati, as far as the root of the uvula, and unites with its fellow. Its use is to draw the velum pendulum palati upwards and backwards, so as to shut the passage from the fauces into the mouth and nose.

LEVATOR PALATI MOLLIS. See Levator palati.

LEVATOR PALPEBRÆ SUPERIORIS. Aperiens palpebrarum rectus. Apertor oculi. A proper muscle of the upper eyelid, that opens the eye, by drawing the eyelid upwards. It arises from the upper part of the foramen opticum of the sphænoid bone, above the rectus superior oculi, near the trochlearis, and is inserted by a broad thin tendon into the cartilage that supports the upper eyelid.

LEVATOR PARVUS. See Transversus pe-

LEVATOR SCAPULÆ. A muscle situated on the posterior part of the neck, that pulls the scapula upwards and a little forwards. This name, which was first given to it by Riolanus, has been adopted by Albinus. Douglas calls it elevator seu musculus patientia; and Winslow; angularis vulgo levator proprius. It is a long muscle, nearly two inches in breadth, and is situated obliquely under the anterior edge of the trapezius. It arises tendinous and fleshy from the transverse processes of the four and sometimes five superior vertebræ colli, by so many distinct slips, which soon unite to form a muscle that runs obliquely downwards an outwards, and is inserted by a flat tendon into the upper angle of the scapula. Its use is to raise the scapula upwards, and a little for-

LEVIGATION. The reduction of hard substances, by triture, to impalpable pow-

LEVISTICUM. (From levo, to assuage; so called from the rehef it gives in painful flatulencies.) Lovage. The odour of this plant, Ligustrum leviscicum of Linnaus: foliis multiplicibus, joliolis suberne incisis, is very strong, and particularly ungrateful; its taste is warm and aromatic. It abounds with a yellowish guniny resinous juice, very much resembling opoponax. Its virtues are supposed to be similar to those of angelica and master-wort, in expelling

flatulences, exciting sweat, and opening obstructions; therefore it is chiefly used in hysterical disorders and atterne obstructions. The leaves, eaten in salad, are accounted emmenagegue. The root, which is less ungrateful than the leaves, is said to possess similar virtues, and may be employed in powder.

LEXIPHARMACA. (From Ana, to terminate, and φαςμακώ, poison ) Medicines which resist or destroy the power of poi-

LEXIPPRETA. (From Aga, to make cease, and mugeros, a fever.) Febrifuge medicines.

LIBADIUM. (From Nica ? w, to make moist; so called because it grows in watery places.) The lesser centaury.

LIBANOTIS. (From Marzs, frankincense so called from its resemblance in smell to

frankincense.) Rosemary.
LIBANUS. (From Libanon, a mountain in Syria, where it grows.) The frankin- -

cense-tree.

LIBOS. (From Ausa, to distil.) A rheum

or defluxion from the eyes.
LIBURNUM. (From Liburnia, the country where it flourished.) The mealy-

Lichanus. (From λειχω, to lick; so call-

ed because it is commonly used in licking up any thing.) The fore-finger.

LICHEN. (AUXIN, or AUXIN, a tetter or ring-worm.) Lichen is, by Dr. Wallen, defined an extensive eruption or papulæ affecting adults, connected with internal disorders, usually terminating in scurf, recurrent, not contagious. The varieties of lichen he considers under the dencininations of Lichen sin plea, Lichen agraus Lichen pilaris, Lichen tividus, and Lichen tropicus.

1. The Licken simplex usually commences with head-ache, flushing of the face, loss of appetite, general langour, and encreased quickness of the pulse. Distinct red papulæ arise first about the cheeks and coin, or on the arras; and, in the course of three or four days, the same appearance takes place on the neck, body, and lower extremities, accompanied with an unpieasant sensation of tingling, which is somewhat aggravated during the night. In about a week the colour of the cruption fade, and the cuticle begins to separate; the whole surface is at tength covered with searly exfoliations, . hich are par icularly large, and continue longest in the fictures of the joints. The duration of the complaint is seldon in any two cases alike; ten, fourteen, seventeen, or sometimes twenty days intervene betwixt the eruption and the renovation of the cuticle. The febrile state. or rather the state of irritation at the beginning of this disorder, is seldom considerable enough to confine the patient to the house. After remaining five or six

days, it is generally relieved on the appearance of the eruption. This, as well as some other species of the lichen, occurs about the beginning of summer, or in autumn, more especially affecting persons of a weak and irritable habit; lience women are more liable to it than men. Lichen simplex is also a frequent sequel of acute diseases, particularly fever and catarrhal inflammation, of which it seems to produce a crisis. In these cases the eruption has been termed, by medical writers, scabies critica. Many instances of it are collected under that title by Sauvages, Nosol. Method. Class x. Order 5. Impetigines.

2. The Lichen agrius is preceded by nausea, pain in the stomach, head-ache, loss of strength, and deep-seated pains in the limbs, with fits of coldness and shivering; which symptoms continue several days, and are sometimes relieved by the papulous eruption. The papulæ are distributed in clusters, or often in large patches, chiefly on the arms, the upper part of the breast, the neck, face, back, and sides of the abdomen; they are of a vivid red colour, and have a redness, or some degree of inflammation, diffused round them to a considerable extent, and attended with itching, heat, and a painful tingling. Dr. Willen has observed, in one or two cases where it was produced from imprudent exposure to cold, that an acute disease ensued, with great quickness of the pulse, heat, thirst, pains of the bowels, frequent vomiting, head-ach, and delirium. After these symptoms had continued ten days, or somewhat longer, the patient recovered, though the eruption did not return. The diffuse redness connecting the papulæ, and the tendency to become pustular, distinguish the lichen agrius from the lichen simplex, and the other varieties of this complaint, in which the inflammation does not extend beyond the basis of the papulæ, and which terminates in scurf, or scales.

3. Lichen pilaris. This is merely a modification of the first species of lichen, and, like it, often alternates with complaints of the head, or stomach, in irritable habits. The peculiarity of the irruption is, that the small tubercles or asperities appear only at the roots of the hairs of the skin, being probably occasioned by an enlargement of their bulbs, or an unusual fulness of the bloodvessels distributed to them. This affection is distinguishable from the cutis anserina, by its permanency, by its red papulæ, and by the troublesome itching or tingling which attends it. If a part thus affected be violently rubbed, some of the papulæ enlarge to the size of wheals, but the tumour soon subsides again. The eruption continues more or less vivid for about ten days, and terminates, as usual, in small

exfoliations of the cuticle, one of which surrounds the base of each hair. This complaint, as likewise the lichen agrus, frequently occurs in persons accustomed to drink largely of spirituous liquors undiluted.

4. Lichen lividus. The papulæ characterizing this eruption are of a dark red, or livid hue, and somewhat more permanent than in the foregoing species of lichen. They appear chiefly on the arms and legs, but sometimes extend to other parts of the body. They are finally succeeded, though at very uncertain periods, by slight exfoliations of the cuticle, after which a fresh eruption is not preceded nor attended by any febrile symptoms. It principally affects persons of a weak constitution, who live on a poor diet, and are engaged in laborious occupations. Young persons, and often children, living in confined situations, or using little exercise, are also subject to the lichen lividus; and in them, the papula are generally intermixed with the petechia, or larger purple spots, resembling vibices. This circumstance points out the affinity of the lichen lividus with the purpura, or land-scurvy, and the connection is further proved by the exciting causes, which are the same in both complaints. The same method of treatment is likewise successful in both cases. They are presently cured by nourishing food, moderate exercise in the open air, along with the use of Peruvian and vitriolic acid, or the tincture of muriated steel.

5. Lichen tropicus. By this term is expressed the prickly heat, a papulous eruption, almost universally affecting Europeans settled in tropical climates. The prickly heat appears without any preceding disorder of the constitution. It consists of numerous papulæ, about the size of a small pin's head, and elevated so as to produce a considerable roughness on the skin. The papulæ are of a vivid red colour, and often exhibit an irregular form, two or three of them being in many places united together; but no redness or inflammation extends to the skin in the interstices of the papulæ.

LICHEN CANINUS. The systematic name of the ash-coloured ground liver-wort. See Lichen cinereus terrestris.

LICHEN CINEREUS TERRESTRIS, Muscus caninus. This cryptogamious plant, called ash-coloured ground liver-wort, and scientifically, Lichen caninus by Linnæus, has a weak, faint smell, and a sharpish taste. It was for a long time highly extolled as a medicine of singular virtue, in preventing and curing that dreadful disorder which is produced by the bite of rabid animals, but now deservedly forgotten. See Pulvis antilyssus.

LICHEN COCCIFERUS. See Muscus pyxi-

datus.

LICHEN ISLANDICUS. The medicinal qualities of the lichen islandicus have lately been so well established at Vienna, that this plant is now admitted into the materia medica of the Edinburgh pharmacopœia. It is extremely mucilaginous, and to taste is bitter, and somewhat astringent. Its bitterness, as well as the purgative quality which its manifest, in its recent state, are in a great measure dissipated on drying, or may be extracted by a slight infusion in water, so that the inhabitants of Iceland convert it into a tolerably grateful and untritive food. An ounce of this lichen, boiled a quarter of an hour in a pint of water, yielded seven ounces of a mucilage as thick as that procured by the solution of one pint of gum-arabic in three of

The medical virtues of this lichen were probably first learned from the Icelanders, who employ it in its fresh state as a laxative; but when deprived of this quality, and properly prepared, we are told that it is an efficacious remedy in consumptions, coughs, dysenteries, and diarrhoas. Scopoli seems to have been the first, who, of late years, called the attention of physicians to this remedy in consumptive disorders: and further instances of its success are related by Herz, Cramer, Tromsdorff, Ebcling, Paulisky, Stoll, and others, who bear testimony of its efficacy in most of the other complaints above-mentioned. Herz says, that since he first used the lichen in dysentery, he found it so successful, that he never had occasion to employ any other remedy; it must be observed, however, that cathartics and emetics were always repeatedly administered before he had recourse to the lichen, to which he also occasionally added opium. Dr. Chrichton informs us, that during seven months residence at Vienna, he had frequent opportunities of seeing the lichen islandicus tried in phthisis pulmonalis at the general hospi-tals, and confesses, "that it by no means answered the expectation he had formed of it." He adds, however, " from what I have scen, I am fully convinced in my own mind that there are only two species of this disease where this sort of lichen promises a cure. The two species I hint at are the plithisis hamoptoica, and the plithisis pituitosa, or mucosa. In several cases of these, I have seen the patients so far get the better of their complaints as to be dismissed the hospital cured, but whether they remained long so or not I cannot take upon me to say." That this lichen strengthens the digestive powers, and proves extremely nutritious, there can be no doubt; but the great medicinal efficacy attributed to it at Vienna will not readily be credited at London. It is commonly given in the form of a decoction; an ounce and a half of the lichen being boiled in a quart of ligaments is to connect the extremities of

milk. Of this a tea-cupful is directed to be drank frequently in the course of the day. If milk disagree with the stomach, a simple decoction of the lichen in water is to be used. Care ought to be taken that it be boiled over a slow fire, and not longer than a quarter of an hour.

The systematic LICHEN PIXIDATUS. See Muscus pyxiname of the cup-moss.

LICHEN PLICATUS. The systematic name of the Muscus arboreus. See Muscus arboreus.

LICHEN PULMONARIUS. The systematic name of the officinal muscus pulmonarius quercinus. See Pulmonaria arborea.

LICHEN ROCCELLA. T'he name of the rocella of the shops. Roccella.

The systematic LICHEN SAXATILIS. name of the museus crani humani.

LIEN. (From Auss, soft, or smooth.) The spleen.

LIEN SINARUM. The faba Ægyptia.

LIENTERIA. (From Assoc, smooth. evregor, the intestine, and pew, to flow.) The Latins call it levitus intestinorum. Lyentery. Dr. Cullen makes it a species of diarrhæa. See Diarrhaa.

LIFE. To live, may be defined the property of acting from an intrinsic power; hence the life of an animal body appears to be three-fold. 1. Its chymical life, which consists in that attraction of the clements, by which the vital principle, diffused through the solids and fluids, defends all the parts of the body from putrefaction. In this sense it may be said, that every atom of our body lives chymically, and that life is destroyed by putrefaction alone. 2. Its physical life, which consists in the irritability of the parts. This physical property remains for some time after death. Thus the heart or intestines, removed from the body whilst still warm, contract themselves on the application of a stimulus. In like manner the serpent, or cel, being cut into pieces, each part moves and palpitates for a long time afterwards. Hence these parts may be said to live *physically*, as long as they continue warm and soft. 3. Its physiological life consists in the action of inorganic parts proper to each, as the action of the heart and vessels; so that, these actions ceasing, the body is said to be physiologically dead. The physiological life ceases first, next the physical, and finally the chymical perishes.

LIGAMENT. (From ligo, to bind.) Li-

gaments are elastic and strong men branes connecting the extremities of the moveable They are divided into capsular, bones. which surround joints like a bag and connecting ligaments. The use of the capsular the moveable boxes, and prevent the efflux of synoria; the external and internal connecting liraments strengthen the extremities or the moveable bones.

A Vable of the principal Ligaments: Ligaments of the lower jaw. The condyles of the lower jaw are connected with the articular smales of the temporal bone by two ligaments, the capsular and lateral ligament.

Ligaments of the occipital bone, and vertebre of the neck. The condyles of the occipital bone are united with the articular depressions of the first vertebræ by the capsular, broad, anterior, and posterior ligaments, the ligaments of the odontoid

process, and ligamentum nuchæ.

Ligaments of the vertebræ. The vertebræ are connected together by means of their bodies and oblique processes. The bodies by a soft cartilaginous substance, and the processes by ligaments, viz. the transverse ligament of the first vertebræ; the anterior and posterior common; the interspinous; the intertransverse; the intervertebral ligements; the capsular ligaments of the oblique processes; and the ligaments of the last vertebræ of the loins with the os sacrum.

Ligaments of the ribs. The posterior extremity of the ribs is united with the vertebræ; the anterior with the sternum. ligaments of the posterior extremity are, the capsular ligaments of the greater and lesser heads; the internal and external ligaments of the neck of the ribs; and a ligament peculiar to the last rib. ligaments of the anterior extremity are, the capsular ligaments of the cartilages of the true ribs, and the ligaments of the ribs

Ligaments of the sternum. The ligaments connecting the three portions of the sternum to the ribs are, the membrana propria of the sternum; and the ligaments of the ensiform

cartilage.

Ligaments of the pelvis. The ligaments which connect the ossa innominata with the os sacrum are, three ligamenta ileo sacra; two sacro-ischiatic lighments; two transverse ligaments of the pelvis; the ligamentum obturans of the foramen ovele, and the ligamentum Poupartii, or inguinale. See Pelvis.

Ligaments of the os coccygis. The basis of the es coccygis is connected to the apex of the os sacrum, by the capsular and lon-

gitudinal ligaments.

Ligaments of the clavicle. The arterior extremity is connected with the sternum and first rib; and the posterior extremity with the acromion of the scapula, by the interclavicular, the capsular ligament, the ligamentum rhomboideum, and in the posterior extremity, the capsular ligament.

Liguments of the scapula. The proper ligaments which connect the scapula with the posterior extremity of the clavicle are. the consi and trapezoil ligaments.

Ligaments of the humerus. of the humerus is connected with the glenoid cavity of the scapula by the capsular

Ligaments of the articulation of the cubit. The elbow-joint is formed by the inferior extremity of the humerus, and superior extrendities of the umar and radius. The ligaments connecting these bones are, the capsular, the brachto-cubitai, and the brachio-radial ligamen's.

Ligaments of the radius. The radius is affixed to the humerus, cubit, and carpus, by peculiar ligaments, namely, the superior, inferior, oblique, and interesseous liga-

Ligaments of the carpus. The ligaments which connect the eight bones of the wrist together, and with the fore-arm and metacarpus, are, the capsular ligament of the carpus; the first and second transverse ligament; the oblique ligaments, and the capsular ligament proper to the bones of the carpus.

Ligaments of the metacarpus. The bones of the metacarpus are in part connected with the second row of bones of the carpus, and in part together, by the articular and

interesseous ligaments.

Ligaments of the fingers. The fingers and phalanges are connected together, and with the metacarpus; and the thumb with the carpus, by the lateral ligaments of the fingers, and garment of the thumb with the os trapezium of the carpus.

Ligaments which keep the tendons of the muscles of the hand in their proper place. The ligaments which keep the tendons of the muscles of the hand in their place, are situated partly on the palm and partly on the back of the hand. In the back of the hand are, the external transverse ligament of the carpus, the vaginal, and the transverse ligaments of the extensor tendons, In the palm of the hand are, the internal transverse ligament of the carpus, the vaginal or crucial ligaments of the flexor tendons of the phalanges, and the accessory ligaments of the flexor tendons.

Ligaments of the articulation of the femur. The head of the os femoris is strongly annexed to the acetabulum of the os innominatum, by two very strong ligaments, the capsular ligament, and ligamentum teres,

or restraining ligament.

Ligaments of the articulation of the knee. The knee-joint is formed by the condyles of the os femoris, head of the tibia and the patella. The ligaments are the capsular, the posterior, the external and the internal lateral ligaments, the crucial and the alar ligaments, the ligaments of the semilunar cartilages, and ligaments of the patella.

Ligaments of the fibula. The fibula is

connected with the tibia by means of the capsular ligament of the superior extremity, the interesseous ligament, and the liga-

ments of the inferior exercitive.

Ligaments of the articulation of the tursus. The inferior extremity of the tibia and fibula forms the cavity into which the astragalus of the tarsus is received. This articulation is effected by the anterior, middle, and posterior ligament of the fibula, the ligamentum tibiæ deltoides, the caspular ligament, and the ligaments proper to the bones of the tashs.

Ligaments of the metatarsus. The bones of the metatarsus are connected in part together, and in part with the tarsns, by means of the capsular ligament, the articular ligaments, the transverse ligaments in the back and sole of the foot, and he interosseous ligaments of the metatarsus.

Ligaments of the toes. The phalanges of the toes are united partly together, and partly with the metatarsus, by the capsular

and lateral ligaments.

Ligaments which retain the tendons of the muscles of the foot in their proper place. These ligaments are found partly in the back, and partly in the sole of the foot. They are the vaginal ligament of the tihia, the transverse or crucial ligaments of the tarsus, the ligaments of the tendon of the peronei muscles, the laciniated liga ent, the vaginal ligament of the extensor muscle and flexor pollicis, the vaginal ligaments of the flexar tendons, the accessory ligaments of the flexor tendons, and the transverse ligaments of the extensor ten-

LIGAMENTUM ANNULARE. The annular ligament. A strong ligament on each

ankle and each wrist.

LIGAMENTUM AUTERIOSUM. The ductus arteriosus of the fœtus becomes a ligament

after birth, which is so called.

LIGAMENTUM CILIARE. Behind the uvea of the human eye there arise, out of the choroid membrane, from the ciliary circle, white complicated strix, covered with a black matter. The fluctuating extremities of these strix are spread abroad even to the crystalline lens, upon which they lie, but are not affixed. Taken together they are called ligamentum ciliare.

LIGAMENTUM DENTICULATUM. A small ligament supporting the spinal

marrow.

LIGAMENTUM FALOPIL The ligamentum rotundum uteri was so called.

LIGAMENTUM INTEROSSEUM. The ligament uniting the radius and ulna, and the tibia and fibula.

LIGAMENTUM LATUM. Broad ligament of the liver and uterus. See Liver, and Uterus.

LIGAMENTUM NUCILE. A strong ligament of the neck, which proceeds from one spinous process to another.

LIGAMENTUM OVARII. The thick round portion of the broad ligament of the uterus, by which the ovarium is connected with the uterus. The ancients supposed this was hollow, to convey the female semen into the uterus.

LIGAMENTUM POUPARTI. pian ligament. Poupart's ligament. ligament extending from the anterior superior spinous process of the ilium to the cris-

ta of the os pubis.

LIGAMENTUM ROTUNDUM, round ligament of the uterus. See Uterus.

LIGATURE (From ligo, to bind.) A thread, or silk, of various thickness, covered with white wax, for the purpose of tying arteries, or veins, or other parts. They should be round and very firm, so as to allow being tied with some force, wit nout

risk of breaking.

The immediate effect of a tight ligature on an artery is to cut through its middle and internal coats, a circumstance that tends very much to promote the adhesion of the opposite sides of the vessel to each other. Hence the form and mole of applying a ligature to an artery should be such, as are most certain of dividing the above coats of the vessel in the most favourable manner. A bread flat ligature does not promise to answer the purpose in the best manner; because it is scarcely possible to tie it smoothly round the artery, which is very likely to be thrown into folds, or to be puckered by it, and consequently to have an aregular bruised wound made in its middle and internal coats. ligature of an irregular form is likely to cut through these coats more completely at some parts than at others; and if it does ant perfectly divide them, no adhesion can take place, and secondary hæmorrhage will follow. A fear of tying the ligature too tight may often lead to the same consequences.

LIGHT. Lux. The nature of light has occupied much of the attention of philosophers, and numerous opinions have been entertained concerning it. It has been sometimes considered as a distinct substance, at other times as a quality sometimes as a cause; frequently as an ef-fect; by some it has been considered as a compound, by others as a simple substance. Philosophers of the present day are not agreed as to the independent existence of light, or the cause by which we

Nature of Light.

Light is that which proceeds from any body producing the sensation of vision. or perception of other bodies, by depicting an image of external objects on the reina of the eye. Hence it announces to animals the presence of the bodies which sur round them, and rables them to distinguish these bodies into transparent, opaque,

3 L "

LIGHT. 4.42

and coloured. These properties are so essentially connected with the presence of light, that bodies lose them in the dark, and

become undistinguishable.

Light is regarded by philosophers as a substance consisting of a vast number of exceedingly small particles, which are actually projected from luminous podies, and which probably never return again to the body from which they were emitted.

It is universally expanded through space. It exerts peculiar actions, and is obedient to the laws of attraction, and other properties

of matter.

Explanation of certain terms of Light.

In order to facilitate the doctrine of light, we shall shortly explain a few terms made use of by philosophers when treating of it; namely:

A ray of light is an exceedingly small portion of light as it comes from a luminous

A medium is a body which affords a pas-

sage for the rays of light.

A beam of light is a body of parallel

A pencil of rays is a body of diverging and

converging rays.

Converging rays are rays which tend to a

common point.

Diverging rays are those which come from a point, and continually separate as they proceed.

The rays of light are parallel, when the

lines which they describe are so.

The radiant point is the point from which diverging rays proceed.

The focus is the point to which the converging rays are directed.

Sources of Light.
Light is emitted from the sun, the fixed stars, and other luminous bodies It is produced by percussion, during electrisation, combustion, and in various other chymical processes.

Why the sun and stars are constantly emitting light is a question, which probably will for ever baffle human understanding.

The light emitted during combustion, exists previously, either combined with the combustible body, or with the substance which supports the combustion. The light liberated during chymical action formed a constituent part of the bodies which act on each other.

Chymical Properties of Light.

The chymical effects of light have much engaged the attention of pholosophers. Its influence upon animal, vegetable, and other substances, is as foilows :

Effects of Light on Vegetubles.

Every body knows that most of the discous flowers follow the sun in his course; that they attend him to his evening retreat, and meet his rising lustre in the morning with the same on rring law. It is also well known that the change of position in

the leaves of plants, at different periods of the day, is entirely owing to the agency of light, and that plants which grow in windows, in the inside of houses, are, as it were, solicitous to turn their leaves towards the light. Natural philosophers have long been aware of the influence of light on vesetation. It was first observed that plants growing in the shade, or darkness, are pale and without colour. The term etiolation has been given to this phenomenon, and the plants, in which it takes place, are said to be etiolated, r blanched. Gardeners avail themselves of the knowledge of this fact, to furnish our tables with white and tender vegetables. When the plants have attained a certain height, they compress the leaves, by young hiem together, and by these means (or by laying earth over them) deprive them of the contact of light: and thas it is that our white celery, lettuce, cabbages, endive, &c are obtained. For the same reason, wood is white under the green b rk; roots are less coloured than plants, some of them alter their taste, &c.; they even acquire a deleterious quality when suffered to grow exposed to light. Potatoes are of this kind. Herbs that grow beneath stones, or in places utterly dark, are write, soft, aqueous, and of a mild and insipid taste. The more plants are exposed to the light, the more colour they Though plants are capable of acquire. being nourished exceedingly well in perfect obscurity, and in that state they even grow much more rapidly than in the sun, (provided the air that surrounds them is fit for vegetation,) they are colourless, and unfit for use.

Professor Davy found, by experiment, that red rose-trees, carefully excluded from light, produce roses almost white. He likewise ascertained that this flower owes its colour to light entering into its composition; that pink, orange, and yellow flowers imbibe a smaller portion of light than red ones, and that white flowers

contain no light.

But vegetables are not only indebted to the light for their colour: taste and odour likewise derived from the same source.

Light contribu es greatly to the maturity of fruits and seeds. This seems to be the cause, why, under the burning sun of Africa, vegetables are in general more odoriferous, of a stronger taste, and more abounding with resin. From the same cause it happens, that hot climates seem to be the native countries of perfumes, odoriterous fruits, and aromatic resins.

The action of light is so powerful on the organism of vegetables, as to cause them to pour forth torrents of pure air from the surface of their leaves into the atmosphere, white exposed to the sun; whereas, on the contrary, when in the shade, they emit an air of a noxious quality. Take a few handsful of fresh-gathered leaves of mint, cabbage, or any other plant; place them in a bell glass, filled with fresh water, and invert it i to a basin with the same fluid. If the whole be then exposed to the direct rays of the sun, small ai bubbles will appear on the surface of the leaves, which will gradually grow larger, and at last detach themselves, and b come collected at the surface of the water. This is oxygen gas, formerly called vital air.

All plants do not emit this air with the same facility; there are some which yield it the moment the sun acts upon them, as the jacobox, or rag-wort lavender, peppermint, and some other aromatic plants. The leaves afford more air when attached to the plant than when gathered; the quantity is also greater, the fresher and sounder they are, and if full grown and collected during dry weather. Green plants afford more air than those which are of a yellowish or white colour. Green fruits afford likewise oxygen gas; but it is not so pl ntifully furnished by those which are ripe. Flowers in general render the air noxious. The nasturtium indicum, in the space of a few hours, gives out more air than is equal to the bulk of all its

On the contrary, if a like bell-glass, prepared in the same manner, be kept in the dark, another kind of air will be disengaged, of an opposite quality.

There is not a substance, which, in wellclosed glass vessels, and exposed to the sun's light, does not experience some al-

Camphor kept in glass bottles, exposed to light, chrystallizes, or vegetates, into the most beautiful symetrical figures, on that side of the glass which is exposed to the light.

Yellow wax, exposed to the light, loses its colour, and becomes hleached. Gum gualacum, reduced to powder, becomes green, on exposure to light. Vegetable colours, such as those of saffron, logwood, &c. become pale, or white, &c.

2. Effects of Light on Animals.

The human being is equally dependent on the influence of light.

Animals in general droop when deprived of light, they become unhealthy, and even sometimes die. When a man has been long or fined in a dark dungeon, (though well aired,) his who e complexion becomes sallow; ous ules, filled with aqueous humours, break out on his skin; and the person who has been thus deprived of light becomes languid, and frequently dropsical.

Worms, rubs, and citerpliers, which live in the earth, or in wood, are of a white h colour; modes, and other insects of the night, are likewise distinguishable from those which fly by day by the want of brilliancy in their colour. The difference between those insects, in northern and southern parts, is still more obvious.

LIG

The parts of fish which are exposed to light, as the back, fins, &c. are uniformly coloured, but the belly, which is deprived

of light, is white in all of them.

Birds which inhabit the tropical countries have much brighter plumage than those of the north. Those parts of the birds which are not exposed to the light are uniformly pale. The feathers on the belly of a bird are generally pale, or white; the back, which is exposed to the light, is alm ist always coloured; the breast, which is particularly exposed to light in most birds, is brighter than the belly.

Butterflies, and various other animals of equatorial countries, are hrighter coloured than those of the polar regions. Some of the northern animals are even darker in

summer and paler in winter.

3 Effects of Light on other Substances. Metailic oxyds become combustible when exposed to light. Acids are decomposed by its contact, and various other substances change their nature.

Light carbonated hydrogen. See Carbo-

nated hydrogen, light.

LIGNUM AGALLOCHI VERI. See Lignum aloes.

LIGNUM ALOES, Lignum agallochi veri. Lignum calambac. Lignum aspalathi. Xyto aloes. Agallochum. Calambac. Aloes-wood. The tree whose wood bears this name is not yet scientifically known. It is imported from China in small, compact, ponderous pieces, of a yellow rusty brown colour, with black or purplish veins, and sometimes of a black colour. It has a bitterish resmous taste, and a slight aromatic smell. It is used to fumigate rooms in castern countries,

LIGNUM ASPALATHI. See aloes,

LIGNUM CALAMBAC. See Lignum aloes.

LIGNUM CAMPECHENSE, pecheusis; so called because it was brought from Campeachy, in the bay of Honduras.) Liguum campechianum. Lignum campescanum. Lignum indicum. Lignum sappan, Logwood. The wood of the Hematoxylum campechyanum of Linnæus; it is of a solid texture and of a dark red colour. It is imported principally as a substance for dieing, ou into junks and logs of about three feet in length: of these pieces the largest and luck st are preserved, as being of the deepest colour. Logwood has a sweetish subadstringent taste, and no remarkable smell: it gives a purp ish red tineture both to wat ry and springues ir fusions, and tinges to stands, and sometimes the urine, of the some colour. It is employed medicinally as an adstringent and corroborant.

th diarrhoas it has been found peculiarly efficacious, and has the recommendation of some of the first medical authorities; also in the latter stages of dysentery, when the obstructing causes are removed, to obviate the extreme laxity of the intestines, usually superinduced by the repeated dejections. In the form of decoction the proportion is two ounces to 2 lbs. of fluid, reduced by boiling to one. An extract is ordered in the pharmacopaias. The dose from ten to forty grains.

LIGNUM INDICUM. See Guaiacum.

LIGNUM MOLUCCENSE. See Lignum pa-

LIGNUM NEPHRITICUM. Nephritic wood. The wood of the Guilandini moringu; inermits foliis sub-bipinnatis, foliis inferioribus ternatis of Linnæus, which also affords the nux bean. It is brought from America in large, compact, ponderous pieces, without knots, the outer part of a whitish or pale yellowish colour, the inner of a dark brown, or red. When rasped, it gives out a faint aromatic smell. It is never used medicinally in this country, but stands high in reputation abroad, against difficulties of making urine, nephritic complaints, and most disorders of the kidneys and urinary passages.

LIGNUM PAVANE. Lignum pavanum.
Lignum moluccense. The wood of the Croton tiglium; foliis ovatis glabris acuminatis serratis, caule arboreo of Linnæus, which affords the grana tiglii. It is of a light spongy texture, white within, but covered with a greyish bark; and possesses a pungent, caustic taste, and a disagreeable smell. It is said to be useful as a purga-

tive in hydropical complaints.

LIGNUM RHODIUM. See Rhodium lig-

LIGNUM SANCTUM. See Guniacum.

LIGNUM SANTALI RUBRI. See Santalium rubrim.

LIGNUM SAPPAN. See Lignum campechense.

LIGNUM SERPENTUM. The wood of the Ophyoxilum serpentinum of Linnaus. It is said to be an alexipharmic.

LIGUSTICUM LEVISTICUM. The systematic ame of lovage. See Levisticum.

LIGUSTRUM. (From ligo, to bind; so hamed from its use in making bands.) 1. The same of a genus of plants in the Linnaan system. Class, Diandria. Order, Monogynia.

2. The pharmacopoial name of the herb

privet.

LILIAGO. (Dim. of lilium, the lily; so named from the resemblance of its flower to that of a lily.) Liliastrum. Spiderwort; formerly said to be alexipharmic and carminitive.

LILIUM. (From hose, smooth, graceful; so named from the beauty of its leaf.)

The name of a genus of plants in the Linnau system. Class, Hexandria. Order, Monogynia. The bly.

LITUM ALRUM The white lily, The roots of the common white lily, Lilium candidum of Linnaus:—foliis sparsis, co-rollis campanulatis, intus glabris, are directed by the Edinburgh pharmacopaia; they are extremely mucilaginous, and chiefly used boiled in milk and water, in emollient and suppurating cataplasms, to inflammatory tuniours. These lily-roots afford a good substitute, in times of scarcity, for bread. The distilled water has been sometimes used as a cosmetic.

LILIUM CANDIDUM. The systematic name of the white lily. See Lilium album.

LILIUM CONVALLIUM. Convallaria. Maianthemum. Convallaria maialis. Lily of the valley. May-lily. The flowers of this plant, Convallaria majalis, scapo nudo of Linnauts, have a penetrating bitter taste, and are given in nervous and catarrhal disorders. When dried and powdered they prove strongly purgative. Watery or spirituous extracts made from them, given in doses of a scruple, or drachm, act as gentle stimulating aperients and laxatives, and seem to partake of the purgative virtue as well as the bitterness of aloes. The roots, in the form of tincture, or infusion, act as a sternutatory when snuffed up the nose, and as a laxative or purgative when taken internally.

Lily, May. See Lilium convallium. Lily, white. See Lilium album.

Lily, water. See Nymphæa alba and Nymphæa lutea.

Lily of the valley. See Lilium conval-

LIMATURA FERRI. Steel filings are considered as possessing stimulating and strengthening qualities, and are exhibited in worm cases, ataxia, leucorrhœa, diarrhœa, chlorosis, &c.

LIMAX (From himus, slime; so named from its sliminess.) Cochlea terrestris. The snail. This animal abounds with a viscid slimy juice, which is readily given out, by boiling, to milk or water, so as to render them thick and glutinous. These decoctions are apparently very nutritious and demulcent, and are recommended in consumptive cases

and emaciations.

LIME. Calx. An earth found in great abundance in nature, though never pure, or in an uncombined state. It is always united to an acid, and very frequently to the carbonic acid, as in chalk, common lime-stone, marble, calcareous spar, &c. It is contained in the waters of the ocean; it is found in vegetables; and is the ba-is of the bones, shells, and other hard parts of animals. Its combination with sulphuric acid is known by the name of sulphate of lime (gypsun, or plaster of Paris.) Com-

bined with fluoric acid it constitutes fluate

of lime, or Derbyshire spar.

Properties.-Lime is in solid masses, of a white colour, moderately hard, but easily reducible to powder. Its taste is bitter, urinous, and burning. It changes blue cabbage juice to a green. It is unalterable by the heat of our furnaces. It splits and falls into powder in the air and loses its strong taste. It is augmented in weight and in size by slowly absorbing water from the atmosphere. Its specific gravity is It combines with phosphorus by heat. It unites to sulphur both in the dry and humid way. It absorbs sulphurated hydrogen gas. It unites with some of the metallic oxyds. Its slaking by water is attended with heat, hissing, splitting, and swelling up, while the water is partly consolidated and partly converted into vapour; and the lime is reduced into a very voluminous dry powder, when it has been sprinkled with only a small quantity of water. It is soluble when well prepared in 300 parts of It unites to acids. It renders silex and alumine fusible, and more particularly these two earths together.

Method of obtaining Line.—Since the carbonic acid may be separated from the native carbonate of lime, this becomes a means of exhibiting the lime in a state of tolerable purity. For this purpose introduce into a porcelam or earthen retort, or rather into a tube of green glass, well coated over with lute, and placed across a furnace, some powdered Carara marble, or oyster-shell powder. Adapt to its lower extremity a bent tube of glass, conveyed under a bell. If we then heat the tube, we obtain carbonic acid gas; and hme will be found remaining in the tube, or retort.

The burning of lime in the large way, depends on the disengagement of the carbonic acid by heat; and, as lime is infirsible in our furnaces, there would be no danger from too violent a heat, if the native carbonate of lime were perfectly pure; but as this is seldom the case, an extreme degree of heat produces a commencement of vitrification in the mixt stone, and enables it to preserve its solidity, and it no longer retains the qualities of lime, for it is covered with a sort of crust, which prevents the absorption of the water when it is attempted to be slaked. This is called over-burnt lime.

In order to obtain lime in a state of great purity, the following method may be had

recourse to.

Take Carara marble, or oyster-shells ; reduce them to powder, and dissolve the powder in pure acetous acid; precipitate the solution by carbonate of ammonia. Let the precipitate subside, wash it repeatedly in distilled water, let it dry, and then expose it to a white heat for some hours.

The acetous acid, in this operation, unites to the lime, and forms acetite of lime, disengaging at the same time the carbonic acid, which flies off in the gazeous state: on adding to the acetite of lime carbonate of ammonia, acetite of aminonia and an artificial carbonate of lime are formed; from the latter the carbonic acid is again expelled, by exposure to heat, and the lime is behind, in a state of perfect purity.

Lime tree. See Tilia.

Lime-water. See Liquor calcis. LIMES. A fruit like a small lemon, the juice of which is a very strong acid, and very much used in the making of punch. Externally, the same acid is applied in the cutaneous affections of warm climates, and also as a remedy against the pains that precede the appearance

LIMON. (Hebrew.) Limonia mala. Malus limonia acida. Citrea malus. Citrus. The lemon. The tree which affords this fruit is the Citrus medica of Linnaus :petiolis linearibus: a native of the upper part of Asia, but cultivated in Spain, Portugal, and France. The juice, which is much more acid than that of the orange, possesses similar virtues. It is always preferred where a strong vegetable acid is required. Saturated with the fixed vegetable alkali, it forms the citrat of potash, which is in frequent extemporaneous use in febrile diseases, and by promoting the secretions, especially that of the skin, proves of considerable service in abating the violence of fever. This medicine is also often employed to restrain vomiting. As an antiscorbntic, the citric acid is also very generally taken on board ships destined for long voyages; but even when well depurated of its mucilaginous parts, it is found to spoil by long keeping. To preserve it in purity for a considerable length of time, it is necessary that it should be brought to a highly concentrated state, and for this purpose it has been recommended to expose the juice to a degree of cold sufficient to congeal the aqueous and mucilaginous parts. After a crust of ice is formed, the juice is poured into another vessel; and, by repeating this process several times, the remaining juice, it is said, has been concentrated to eight times its original strength, and kept, without suffering any material change, for several years. Whytt found the juice of lemons to allay hysterical palpitations of the heart, after various other medicines had been experienced ineffectual; and this juice, or that of oranges, taken to the quantity of four or six ounces in a day, has sometimes been found a remedy in the jaundice. The exterior rind of the lemon is a very grateful, aromatic bitter, not so hot as orange-peal, and yielding in distillation a

less quantity of oil, which is extremely the hereditary? Marshal of Hesse addlight, almost colourless, and generally ed. brought from the southern parts of Europe, under the name of Essence of Lemons. The lemon-peel, though less warm, is similar in its qualities to that of the orange, and is employed with the same in-The Pharmacopæias direct a syrup of the juice, syrupus limonis, and the peel enters into vinous and aqueous bitter infusions; it is also ordered to be candied; and the essential oil is an ingredient in the spiritus ammoniæ compositus, and other for-

LIMONIUM. (From Aupwr, a green field; so called from its colour.) Sea-lavender.

Astringent.

LIMONIUM. (From Auman, a green-field; so called from the colour of its unripe fruit ) The lemon-tree, or citrus medica.

LINAGROSTIS. (From Atyon, cotton, and αγεωτις, grass; so called from the softness of its texture.) Cotton grass.

LINANGINA. (From linum, flax, and ango, to strangle; so called, because it it grows among flax or hemp, it twists round it, and

chokes it.) The herb dodder.

(From linum, flax, named LINARIA. from the resemblance of its leaves to those of flax.) Osyris. Urinaria. Common toadflax. Antirrhinum linaria of Linnæu: :foliis lanceolato linearibus confertis, caule erecto, spicis terminalibus sessilibus, floribus, imbricatis. A parennial indigenous plant, common in barren pastures, hedges, and the sides of roads, flowering from July to to September. The leaves have a bitterish and somewhat saline taste, and, when rubbed between the fingers, have a faint smell, resembling that of elder. They are said to be diuretic and cathartic, and in both characters to act powerfully, especially in the first; hence the name urinalis. They have been recommended in dropsies, and other disorders requiring powerful evacu-The linaria has also been used as a resolvent in jaundice, and such diseases as were supposed to arise from visceral But the plant has been obstructions. chiefly valued for its effects when externally applied, especially in hæmorrhoidal affections, for which both the leaves and flowers have been employed in various forms of ointment, fomentation, and poultice. Dr. Wolph first invented an ointment of this plant for the piles. The Landgrave of Hesse, to whom he was physician, constantly interrogated him, to discover its composition; but Wolph obstinately refused, till the price promised to give him a fat ox annually for the discovery: hence, to the following verse, which was made to distinguish the linarian from the escula, viz.

"Escula lactescit, sine lacte linaria crescit,

" Esula nil nobis, sed dat linaria taurum." LINCTUS. (From lingo, to lick.) Lohoc. Eclegma. Elexis. Elegma. Eclec. tos. Ecleitos. Illinetus. Loch and lambative. A term in pharmacy, that is generally applied to a soft and somewhat oily substance, of the consistence of honcy. which is licked off the spoon, it being too solid and adhesive to be taken otherwise.

LINEA ALBA. (From linum, a thread, and album, white: so called from its appearance and colour.) Linea centralis. An aponeurosis that extends from the scrobiculus cordis straight down to the navel, and from thence to the pubis. It is formed by the tendinous fibres of the internal oblique ascending and the external oblique descending muscles, and the transversalis, interlaced with those of the opposite side.

LINEÆ SEVILUNARES. The lines which bound the outer margin of the recti muscles, formed by the union of the abdomi-

nal tendons.

LINEE TRANSVERSÆ. Lines which cross the recti muscles.

LINGUA. (From lingo, to lick up. The tongue. See Tongue.

LINGUA AVIS. The seeds of the Fraxinus, or ash, are so called, from their supposed resemblance to a bird's tongue.

LINGUA CANINA. So called from the resemblance of its leaves to a dog's tongue. See Cynoglossum.

LINGUA CERVINA. See Scolopendrium.

LINGUALIS. (Lingualis, sc. musculns; from lingua, a tongue.) Basio-glossus of Cowper. A muscle of the tongue. It arises from the root of the tongue laterally, and runs forward between the hyo-glossus and genio-glossus, to be inserted into the tip of the tongue, along with part of the stylo-glossus. Its use is to contract the substance of the tongue, and to bring it backwards.

LINIMENT. (Linimentum; from lino, to anoint.) An oily substance, of a mediate consistence between an ointment and

oil, but so thin as to drop.

The following are some of the most approved forms.

LINIMENTUM ERUGINIS. Liniment of verdigris, formerly called oxymel æruginis, mel Ægyptiacum, and unguentum Ægyptiacum. "Take of verdigris, powdered, an ounce; vinegar, seven fluid ounces; clarified honey, fourteen ounces." Dissolve the verdigris in the vinegar, and strain it through a linen cloth; having added the honey gradually, boil it down to a proper consistence.

LINIMENTUM AMMONIÆ CARBONATIS. Linimentum of carbonat of ammonia, formerly called linimentum ammonia and linimentum volatile. "Take of solution of subcarbonate of ammonia, a finid-ounce; olive oil, three finid-ounces." Shake them together until they unite. A samulating linament, mostly used to relieve rheumatic pains, bruises, and paralytic numbness.

LINIMENTUM AMMONIA FOUTIUS. Strong lininent of ammonia. "Take of solution of animonia, a fluid-ounce; olive oil, two of inid-ounces." Shake them together until they unite. A more powerful stimulating application than the former, acting as a rubefacient. In pleurodyma, indolent tumours, stiffness of the joints, and arthritic pains, it is to be preferred to the milder one.

LINIMENTUM AQUE CALCIS. Linament of lime-water. "Take of lime-water, olive-oil, of each eight onnees; rectified spirit of wine, one ounce." Mix. This has been long in use as an application to burns and scalds.

LINIMENTUM CAMPHORE. Camphor liniment. "Take of camphor, half an ounce. Olive oil, two fluid-ounces." Dissolve the camphor in the oil.

LIMIMENTUM CAMPHORE COMPOSITUM. Compound camplor limment. "Take of camphor, two ounces; solution of ammonia, six fluid-ounces; spirit of lavender, a pint." Mix the solution of ammonia with the spirit in a glass retort; then, by the heat of a slow fire, distil a pint. Lastly, in this distilled liquor, dissolve the eamphor. An elegant and useful stimulant application in paralytic, spasmodic, and rheumatic diseases. Also for bruisgs, sprains, rigidities of the joints, incipient chilbrains, &c &c.

LINIMENTUM HYDRARGYRI COMPOSITUM. Compound mercurial liminent. " Take of strong mercurial ointment, prepared lard, of each four poulds; camphor, an ounce; rectified spirit, fif een minims; solution of ammonia, four fluid-ounces." First powder the camphor, with the addition of the spirit, then rub it with the mercurial ointment and the lard; lastly, add gradually the solution of ammonia, and nux the whole together. An excellent formula for all surpical cases, in which the object is to quicken the action of the absorbents, and gen ly stimulate the surfaces of parts. It is a useful application for diminishing the indurated state of particular muscles, a pecular affection every now and then met with in practice; and it is peculiarly well calculated for tessening the stiffness and chronic thickening often noticed in the joints. If it be frequenly or largely applied, it affects the mouth more rapidly than the mercurial ointment.

LINIMENTUM OPIATUM. A resolvent anodyne embrocation, adapted to remove indolent tumours of the joints, and those weaknesses which remain after strains and chilblains before they break.

LINIMENTUM SAPONIS COMPOSITUM. Compound soap liniment. Linimentum saponis.

"Take of hard's ap, three ounces; camphor, an ounce; spirit of rosenary, a pint." Dissolve the camphor in the spirit, then add the soap, and macerate in the heat of a sand-bath, until it be melted. The basis of this form was first proposed by Riverius, and it is now commonly used under the name of opodeldoc. This is a more pleasant preparation, to rub parts affected with rheumatic pains, swellings of the joints, &c. than any of the foregoing, and at the same time not inferior, except where a rubifacient is required.

LINIMENTUM SAPONIS CUM OPIO. Soap liniment, with opium. "Take of compound soap liniment, six ounces; tincture of opium, two ounces." Mix. For dispersing induracions and swellings, attended with pain, but no acute inflammation.

LINIMENTUM TEREBINTHINE. Turpentine lin.ment "Take of resin of cerate, a pound; oil of turpentine, half a pint." Add the oil of turpentine to the cerate, previously melted, and mix. This liniment is very commonly applied to burns, and was first introduced by Mr. Kentish, of Newcastle.

LINIMENTUM TERREINTHINE VITRIOLICUM. Virriolis limiment of turpentine. "Take of olive oil, ten ounces; oil of turpentine, four ounces; vitriohe acid, three drachms." Mix. This preparation is said to be efficacious in chronic affections of the joints, and in the removal of long existing effects of sprains and bruises.

Liniment of ammonia. See Linimentum ammonia.

Liniment of camphor. See Linimentum camphore.

Liniment of mercury. See Linimentum hydrargyri.

Liniment of verdigris. See Linimentum aruginis.

Limment of turpentine. See Linimentum terebinthing.

LINNÆA. (So named in honour of Linnæus.) The name of a genus or plants in the Lionæan system. Class, *Didynamia*. Orser, *Angiospermia*.

LINNEA BOREALIS. The systematic name of the plant named in honour of the importal Lunguis, which has a bitter subastringent taste, and is used in some places in the form of fomentation to rheumatic pains, and an iniusion with mirk is much esteemed in Switzerland in the cure of sciatica.

Threspendum. (From λυου, flax, and 5πεμα, end) Linseed.

in eed. The runt of the flax plant,

or from, is rouch used in medicine. Its quadries are muchlaginaus and only. It is lubricating and emollient. It is employed

in decoction, or infusion, in heat of urine, &c. in the form of clyster, in tenesmus, in cataplasm, in quincy, and other complaints. The proportion of the seeds in the decoction are, an ounce to a pound of water. See Linum.

Lint. See Linteum.

LINTEUM. Lint. A soft woolly substance, made by the scraping of old linen cloth, and employed in surgery as the common dressing in all cases of wounds and ulcers, either simply or covered with different unctuous substances.

LINUM. (From Assoc,, soft, smooth; so called from its soft, smooth, texture.) 1. The name of a genus of plants in the Linnæan system. Class, Pentandria.

der, Pentagynia.

2. The pharmacopæia name of the common flax. Linum sylvestre. Linum usitatissimum of Linnans :- calycibus capsulisque mucronatis, petalis crenatis, foliis lanceolatis alternis, caule subsolitario. The seeds of this useful plant, called linseed, have an unctuous, mucilaginous, sweetish taste, but no remarkable smell; on expression they yield a large quantity of oil, which, when carefully drawn, without the application of heat, has no particular taste or flavour: boiled in water, they yield a large proportion of a strong flavourless mucilage, which is in use as an emollient or demulcent in coughs, hoarsenesses, and pleuritic symptoms, that frequently prevail in catarrhall affections; and it is likewise recommended in nephritic pains and stranguries. The meal of the seeds is also much used, externally, in emollient and ma-turating cataplasms. The expressed oil is an officinal preparation, and is supposed to be of a more healing and balsamic nature than the other oils of this class: it has, therefore, been very generally employed in pulmonary complaints, and in colics and constipations of the bowels. The cake which remains after the expression of the oil contains the farinacious part of the seed, and is used in fattening cattle, under the name of oil cake.

LINUM CATHARTICUM. Linum minimum. Chamælium. Purging flax, or mill-mountain. This small plant, Linum catharticum, foliis oppositis ovato-lunceolatis, caule dichotomo corollis acutis of Linnæus, is an effectual and safe cathartic. It has a bitterish and disagreeable taste. A handful infused in half a pint of boiling water is the dose for an dault.

The systema-LINUM USITATISSIMUM. tic name of the common flax. See Li-

LIPARIS. (From NITGE, fat; so named from its unctuous quality.) See Pingui-

LIPAROCELE. (From Autos, fat, and инди, a tumour.) That species of sarco-

cele in which the substance constituting the disease is fat.

LIPOMA. (From Airos, fat.) A solitary, soft, unequal, indolent tumour, arising from a luxuriancy of adeps in the cellular membrane. The adipose structure forming the tumour is sometimes diseased towards its centre, and more fluid than the rest. At other times it does not appear to differ in any respect from adipose membrane, except in the enlargement of the cells containing the fat. These tumours are always many years before they arrive at any size.

LIPOPSYCHIA. (From AUTW, to leave, and

Juxn, the soul, or life.) A swoon.

LIPOTHYMIA. (From λυπω, to leave, and  $\theta \nu \mu \sigma s$ , the mind.) Deliquium animi et animæ. Defectio animi; dissolutio. Syncope. Asphyxia. Vi-Exanimatio. rium lapsus. The greatest degree is called Apsychia. Ecchysis. Faint-Apopsychia. Dr. Cullen makes it a genus of disease in the class Neuroses, order Adynamiæ, which he defines the motion of the heart diminished, or at rest for some time. He distinguishes it into three species. Sec Syncope.

LIPPITUDO. (From lippus, blear-eyed.) Epiphora. Yerophthalmia. Blearedness. An exudation of a puriform humour from the margin of the eye-lids. The proximate cause is a deposition of acrimony on the glandulæ meibomianæ in the margin of the eye-lids. This humour in the night glues the tarsi of the eye-lids together. The margins of the eye-lids are red and tumefy are irritated, and excite pain. An ophthalmia, fistula lachrymalis, and sometimes an ectropium, are the consequences. The species of the lippitude are,

1. Lippitudo infantum, which is familiar to children, particularly of an acrimoni-The lippitudo of infants is ous liabit. mostly accompanied with tinea, or some scabby eruption, which points out that the disease originates, not from a local, but general or constitutional, affection.

2. Lippitudo adultorum or senilis. This arises from various acrimonies, and is like.

wise common to hard drinkers.

scorbutic.

3. Lippitudo venerea, which arises from a suppressed gonorrhæa, or fluor albus, and is likewise observed in children born of parents with venereal complaints.

4. Lippitudo scrophulosa, which accom-

panies other scrophulous symptoms. 5. Lippitudo scorbutica, which affects the

LIPYRIA. (From AUTW, to leave, and rug, heat.) A sort of fever, where the heat is drawn to the inward parts, while the external are cold.

LQIUIDAMBER. The name of a genus of plants in the Linnaan system.

The LIQUIDAMBER STYRACIFLUA.

systematic name of the tree which affords both the liquid-amber and liquid storax.

See Liquidambra,

LIQUIDAMBRA. (From liquidus and amber.) Styrax liquida. Liquidamba. Liquid amber. A resmous juice, of a yellow colour, inclining to red, at first about the consistence of turpentine, by age hardened into a solid brittle mass. It is ob ained by wounding the bark of the Liquidamber styraciflua; foliis palmato angulatis; foliis indivisis, acutis, of Linnaus. This juice has a moderately pungent, warm balsamic taste, and a very fragrant smell, not unlike that of the Siyrax calamita heightened by a little ambergris. It is seldom used medicinally. The Styrax liquida is also obtained by boiling from this plant. There are two sorts distinguished by authors; the one, the purer part of the resinous matter, that rises to the surface in boiling, separated by a strainer, of the consistence of lioney, tenacious like turpentine, of a reddish or ash-brown colour, moderately transparent, of an acrid unctuous taste, and a fragrant smell, faintly resembling that of the solid storax, but somewhat disagreeable. The other, the more impure part which remains on the strainer, untransparent, and in smell and taste much weaker than the former. Their use is chiefly as stomachics, in the form of plaster.

LIQUILITIA. (From liquor, juice, or from

elikoris, Welsh.) See Glycyrrhiza.

LIQUOR ATHEREUS VITRIOLICUS. liquor procured from a distillation of equal parts of sulphuric acid and spirit of wine redistilled.

LIQUOR ACETATIS AMMONIÆ. of acetate of ammonia; formerly called Aqua ammonia acetata. "Take of carbonate of ammonia, two ounces; acetic acid, four pints." Add the acid to the salt, until bubbles of gas shall no longer arise, and

If the acid rather predominate, the solution is more grateful to the taste; and provided that acid be correctly prepared, the proportions here given will be found sufficient; where the acid cannot be depended on, it will be right to be regulated rather by the cessation of effervescence

than by quantity.

This preparation was formerly known in the shops under the name of spirit of Minderus. When assisted by a warm regimen, it proves an excellent and powerful sudorific; and, as it operates quickening the circulation, or increasing the heat of the body, it is admissible in febrile and inflammatory diseases, in which the use of stimulating sudorifics are attended with danger. Its action may likewise be determined to the kidneys, by walking about in the cool air. The common dose is half an ounce, either by itself

or along with other medicines, adapted to the same intention.

LIQUOR ACETATIS PLUMBI. Solution of acetate of lead, formerly called aqua lithargyri acetati. Goulard's extract. "Take of vitrified oxyd of lead, two pounds and four ounces; acetic acid, a gallon." Mix, and boil down to six pints, constantly stirring; then set it by, that the feculencies may subside, and strain.

It is principally employed by surgeons, as a resolvent against inflammatory affec-

tions.

LIQUOR ACETATIS PLUMBI DILUTUS. luted solution of acetate of lead. Aqua lithargyri acetati composita. "Take of solution of acetate of lead, a drachm; distilled wa er, a pint; weak spirit, a fluid drachm." Mix. The virtues of this water, the aqua vegeto-mineralis of former pliarmacopaias, applied externally, are resolvent, refrigerant, and sedative.

LIQUOR ALUMINIS COMPOSITUS. pound solution of alum. "Take of alum, sulphate of zinc, of each half an ounce; boiling water, two pints." Dissolve at the same time the alum and sulphate of zinc in the water, and then strain the solution through

paper.

This water was long known in our sliops under the title of aqua aluminosa bateanas. It is used for cleansing and healing ulcers \*\* and wounds, and for removing cutaneous cruptions, the part being bathed with it hot three or four times a-day. It is sometimes likewise employed as a collyrium; and as an injection in fluor albus and gonorrhea, when not accompanied with virulence.

LIQUOR AMMONIE. Solution of ammonia. Aqua ammonia pure of the London Pharm. 'Take of muriate of ammonia, lime, newly prepared, of each two pounds; water, a pint and a half." Reduce the muriate of ammonia and the lime into powder, separately; then mix them, and introduce them into a large glass retort, into which a pint of the water has been previously poured. Having placed the retort in a sand-bath. lute on a tubulated receiver, through which the ammonia may pass into a third vessel. containing half a pint of the water, and cooled. Then at first apply a gentle heat; and increase it by degrees, until the retort becomes red

Water of ammonia is very rarely given internally, although it may be used in doses of ten or twenty drops, largely diluted, as a powerful stimulant in aspinyxia and similar diseases. Externally, it is applied to the skin as a rube "cient, and in the form of gas to the nostrils, and to the eyes as a stimulant; in cases of torpor, paralysis, rheumatism, syncope, hysteria, and chronic ophthalmia.

LIQUOR CARBON TIS AMMONIE. tion of carbonate of aminonia. The aqua

ammoniæ of the Pharm. Lond. 1787. "Take of carbonate of ammonia, eight ounces; distilled water, a pint." Dissolve the subcarbonate of ammonia in the water, and filter the solution through paper. This preparation possesses the properties of ammonia in its action on the human body. See Carbonas ammonie.

Carbonas ammoniæ. LIQUOR AMNII. All that fluid which is contained in the membranac-ous ovum surrounding the fœtus in utero is called by the general name of the waters, the water of the amnien, or ovum, or liquor amnii. The quantity, in proportion to the size of the different parts of the ovum, is greatest by far in early pregnancy. At the time of par-turition in some cases, it amounts to or exceeds four pints; and in others it is scarcely equal to as many ounces. It is usually in the largest quantity when the child has been some time dead, or is born in a weakly state. This fluid is generally transparent, often milky, and sometimes of a yellow, or light brown colour, and very different in consistence; and these alterations seem to depend upon the state of the constitution of the parent. It does not coagulate with he t, like the serum of the blood; and, chymically examined, it is found to be composed of phlegm, earthy matter, and sea salt, in different proportions in different subjects, by which the varieties in its appearance and consistence are produced. It has been supposed to be excrementitious; but it is generally thought to be secreted from the internal surface of the ovum, and to be circulatory, as in other cavities. was formerly imagined, that the fœtus was nourished by this fluid, of which it was said to swal.ow some part frequently; and it was then asserted, that the qualities of the fluid were adapted for its nourishments. But there have been many examples of children born without any passage to the stomach; and a few, of children in which the head was wanting, and which have nevertheless arrived at the full size. cases fully prove that this opinion is not just, and that there must be some other medium by which the child is nourished, besides the waters. The incontrovertible uses of this fluid are, to serve the purpose of affording a soft bed for the residence of the fœtus, to which it allows free motion, and prevents any external injury during pregnancy: and inclosed in the membranes, it procures the most gentle, yet officacious, dilatation of the os uteri, and soft parts, at the time of parturition. Instances have been recorded, in which the waters of the ovum are said to have been voided so early as in the sixth month of pregnancy, without pr. ju 'ice either to the child or parent. The truth of these reports seem to be doubtful, because, when the membranes are intentionally broken, the action of the

uterus never fails to come on, when all the water is evacuated. A few cases have occurred to me, says Dr. Denman, in practice, which might have been construed to be of this kind; for there was a daily discharge of some colourless fluid from the vagina, for several months before delivery; but there being no diminution of the size of the abdomen, and the waters being regularly discharged at the time of labour, it was judged that some lymphatic vessel near the os uteri had been ruptured, and did not close again till the patient was de livered. He also met with one case, in which, after the expulsion of the placenta, there was no sanguineous discharge, but a profusion of lymph, to the quantity of several pints in a few hours after delivery; but the patient suffered no inconvenience, except from surprise.

LIQUOR ANTIMONII TARTANIZATI. Solution of tartarized antimony. Vinum antimonii tartarizati of the Pharm. Lond. 1787. "Take of the tartarized antimony, one scruple; boiling distilled water, four fluid-ounces; wine six fluid-ounces." Dissolve the tartarized antimony in the boiling distilled water, then add the wine. Half an ounce of the solution contains one grain of the salt. This preparation may be given in all cases where the tartar emetic is indi-

cated.

LIQUOR ARSENICALIS. Arsenical solution. "Take of prepared oxyd of arsenic, in very fine powder, subcarbonate of potash from tartar, of each 64 grains; distilled water a pint." Boil them together in a glass vessel, until the arsenic be entirely dissolved. When the solution is cold, add "compound spirit of lavender, four fluid-drachms." Then add as much distilled water as may exactly fill a pint measure. This preparation accords with the formula of Dr. Fowler, of Stafford, who first introduced it in imitation of a celebrated popular remedy for intermittents, sold under the name of the tasteless ague-drop. The compound spirit of lavender is only intended to give some colour and taste, without which it would resemble common water, and hence be more liable to mistakes. Where the dose is small, and the effects so powerful, the most minute attention to its proportion and preparation become necessary. Each ounce contains four grains of the oxyd, and each drachm one-eighth of a grain; but it will rarely be proper to go beyond half the latter quantity, or one-sixteenth of a grain as a dose.

Liquon calcis. Solution of lime, formerly called aqua calcis. Lime-water. "Take of lime, half a pound; boiling distilled water, twelve pirts." Pour the water upon the lime, and stir them together; next cover the vessel immediately, and let it stand for three hours; then keep

the solution upon the remaining lime in stopped glass bottles, and pour off the clear liquor when it is wanted for use.

Lime is soluble in about 450 times its weight of water, or little more than one grain in one fluid-ounce. It is given internally, in doses of two ounces and upwards, in cardialgia, spasms, diarrhea, &c. and in proportionate doses in convulsions of children, arising from acidity, or ulcerated intestines, intermittent fevers, &c. Externally it is applied to burns and ulcers.

LIQUOI CUPRT AMMONIATI. Solution of animoniated copper. Aqua cupri ammoniated Pharm. Lond. 1787, and formerly calied aqua sapharina. "Take of ammoniated copper, a drachm; distilled water, a pint." Dissolve the ammoniated copper in the water, and filter the solution through paper. This preparation is employed by surgeons for cleansing foul uleers, and disposing them to heal.

Liquor Feinh Alkalini. Solition of alkaline iron, "Take of iron, two drachms and a half; nitric acid, two fluid-ounces; distilled water, six fluid-ounces; solution of carbonate of potash, six fluid-ounces."

Having mixed the acid and water, pour them upon the iron, and when the effervescence has ceased, pour off the clear acid solution; add this gradually, and at intervals, to the solution of subcarbonate of potash, occasionally shaking it, until it has assumed a deep brown red colour, and no further effervescence takes place. Lastly, set it by for six hours, and pour off the clear solution. This preparation was first described by Stahl, and called tinctura martis alkalina, and is now introduced in the Lond. Pharm, as affording a combination of iron distinct from any other, and often applicable to practice. The dose is from half a draehm to a drachm.

Liquor oxymuniates hyprargyri. Solution of oxymuniate of mercury. "Take of oxymuniate of mercury, eight grains; distilled water, fifteen fluid-ounces; rectified spirit, a fluid-ounce." Dissolve the oxymuniate of mercury in the water, and add the spirit.

This solution is directed in order to facilitate the administration of divisions of the grain of this active medicine. Half an ounce of it contains one-cighth of a grain of the salt. The dose is from one drachm to half an ounce.

LIQUOR MINEBALIS ANODYNUS HOFF-MANNI Hoffman's anodyne liquor. A preparation of other extolled as an anodyne and antispasmodie. See Spiritus atheris compositi.

Liquor forassæ. Solution of potash, Aqua kali puri. Livivium sapouarium. "Take of subcarbonate of potash, lime, newly prepared, of each a pound. Boiling distilled water, a gallon" Dissolve

the potash in two pints of the water; add the remaining water to the lime. Mix the liquors while they are hot, stir them together, then set the mixture by in a covered vessel; and after it has cooled, strain the solution through a cotton bag

If any diluted acid dropped into the solution occasion the extrication of bubbles of gas, it will be necessary to add more lime, and to strain it again. A pint of this solution ought to weigh sixteen ounces.

LIQUOR SUBCARBONATIS POTASSE. Solution of subcarbonate of potash. Aqua kalipreparati. Lixivium tartari. Oleum tartari per deliquium. "Take of subcarbonate of potash, a pound; distilled water, twelve fluid-ounces." Dissolve the subcarbonate of potash in the water, and then strain the solution through paper.

It possesses antacid virtues, and is a good antidote against arsenic taken into the stomach. It is also given with advantage in convulsions and spasms, from acidity in the stomach of children, in calculous diseases, gouty affections, serophula, aphthæ, &c. The carbonate of soda is milder, and perhaps a preferable remedy for general use. The dose of the liquor potassæ subcarbonatis is from kalf a draehm to a drachm and a half.

LIQUON VOLATILIS CORNU CERVI. This preparation of the valatile alkali, commonly termed hartshorn, possesses the same virtues as the carbonate of ammonia. It is in common use to smell at in faintings, &c. Sce Carbonas ummoniae.

Liquorice. See Glycyrrhiza.
Liquorice, Spanish. See Glycyrrhiza.
Littagoga. (From λθος, a stone, and

αγω, to bring away) Medicines which expel the stone.

Litharge. See Lithargyrus.

Litharge plaster. See Emplastrum li

thargyri.

LITHARGURUS. (From 1,100c, a stone, and agyoges, silver.) Lithargyrum. A subcarbonate of lead, in an imperfect state of vitrification. When silver is refined by cupellation with lead, this latter metal, which is scorified, and causes the scorification of the imperfect metals alloyed with the silver, is transformed into a matter composed of small semitransparent shining plates, resembling mica; which is litharge. Litharge is more or less white or red, according to the metals with which the silver is alloyed. The white is called litharge of silver; and the red has been improperly called litharge of gold. See Lead, Liquor plumbi acetatis, and Liquor plumbi acetatis dibutus.

LITHIAS. A lithiate, or salt, formed by the union of the lithic acid, or acid of the stone sometimes found in the human bladder, with different bases; thus, lithiate of alumine, lithiate of ammonia, &c.

LIT LITHIASIS. (From Ailos, a stone.) The formation of stone, or gravel.

2. A tumour of the eyelid, under which is a hard concretion resembling a stone.

LITHOBALUM. (From Ailos, a stone, and λαμβανω, to seize.) An instrument for extracting the stone from the bladder.

LITHOIDES. (From Aidos, a stone, and exoc, a likeness; so called from its hardness.) The petrous portion of the temporal

LITHOLOGY. (Lithologia; from \u03b1θος, a stone, and λογος, a discourse.) A discourse or treatise on stones.

LITHOMARGA. Stone marle. Fuller's earth is one of the most useful varieties of

lithomarge.

LITHONTRIPTICS. (Lithontriptica, sc. medicamenta; from xibos, a stone, and θουπτω, to break.) From the strict sense and common acceptation of the word, this class of medicine should comprehend such as possess a power of dissolving calculi inthe urinary passages. It is, however, doubted by many, whether there be in nature any such substances. By this term, then, is meant those substances which possess a power of removing a disposition in the body to the formation of The researches of modern chycalculi mists have proved, that these calculi consist mostly of a peculiar acid, named the lithic or uric acid. With this substance the alka-lies are capable of uniting, and forming a soluble compound; and these are accordingly the sole lithontriptics. From the exhibition of alkaline remedies, the symptoms arising from stone in the bladder are very generally alleviated; and they can be given to such an extent that the urine becomes very sensibly alkaline, and is even capable of exerting a solvent power on these concretions. Their administration, however, cannot be continued to this extent for any length of time, from the irritation they produce on the stomach and urinary organs. The use, therefore, of the alkalies, as solvents, or lithrontriptics, is now scarce. ly ever attempted; they are employed merely to prevent the increase of the concretion, and to palliate the painful symptoms, which they do apparently by preventing the generation of lithic acid, or the separation of it by the kidneys; the urine is thus rendered less irritating, and the surface of the calculus is allowed to become smooth.

When the alkalies are employed with this view, they are generally given saturated, or supersaturated, with carbonic acid. This renders them much less irritating. It at the same time, indeed, diminishes its solvent power; for the alkaline carbonates exert no action on urinary calculi; but they are still capable of correcting that acility in the primæ viæ, which is the cause

the urine, and therefore serve equally to palliate the disease. And when their acrimony is thus diminished, their use can be continued for any length of time.

It appears from the experiments of Fourcroy, and others, that the other ingredients of calculi, as well as the lithic acid, are dissolved by the caustic alkali, and various experiments have shewn that most calculi yield to its power. Lime-water has also been found a solvent of urinary calculi, out of the body. It is obvious, however, that what is taken by the mouth is subject to many changes in the alimentary canal, and also the lymphatic and vascular systems; and in this way, it must be exceedingly difficult to get such substances (even were they not liable to alterations) in sufficient quantity into the bladder. Indeed there are very few authent cated cases of the urine being so changed as to become a menstruum for the stone. Excepting the case of Dr. Newcombe, recorded by Dr. Whytt, the instance of Mr. Home is almost the only one. Though lithoutriptics, however, may not in general dissolve the stone in the bladder, yet it is an incontrovertible fact that they frequently mitigate the pain; and, to lessen such torture as that of the stone in the bladder, is surely an object of no little importance. Lime was long ago known as a solvent of urinary calculi, and different methods were employed to administer it. One of these plans fell into the hands of a Mrs. Steevens, and her success caused great anxiety for the discovery of the secret. At last, Parliament bought the secret for the sum of 5000l. In many instances, stones which had been unquestionably felt were no longer to be discovered; and as the same persons were examined by the greatest skill and eminence, both before and after the exhibition of her medicines, it was no wonder fthat the conclusion was drawn, that the stones really were dissolved. From the cessation of such success, and from its now being known that the stones are occasionally protruded between the fasciculi of the muscular fibres of the bladder, so to be lodged in a kind of cyst on the outside of the muscular coat, and cause no longer any grievances, surgeons of the present day are inclined to suspect that this must have happened in Mrs. Steevens's cases. This was certainly what happened in one of the cases on whom the medicine had been tried. It is evident that a stone so situated would not any longer produce irritation, but would also be quite indiscoverable by the sound, for, in fact, it is no longer in the cavity of the bladder.

As soap was, with reason, supposed to increase the virtues of the lime, it led to the use of caustic alkali, taken in mucilage, of the deposition of the lithic acid from or yeal broth. Take of kali, prepared, Zviij; of quick lime Ziv; of distilled water, Ibij. Mix them well together in a large bottle, and let them stand for wenty four hours. Then pour off the ley, filter it through paper, and keep it in well-stoppped vials for use. Of this, the dose is from thirty drops to Zij, which is to be repeated two or three times a-day, in a pint of veal broth, early in the morning, at noon, and in the evening. Continue this plan for three or four mouths, living, during the course, on such things as least counteract the effect of the medicine.

The common fixed alkalis, or carbonated alkali, and the acidulous soda-water, have of late been used as lithontriptics. Honey has also been given, and Mr. Home, surgeon at the Savoy, has recorded its utility in his own and his father's cases. Bitters

have likewise been tried.

Dismissing all theories, lime-water, soap, acidulous soda-water, caustic alkali, and bitters, are useful in cases of stone. Of the soap, as much may be taken as the stomach will bear, or as much as will prove gently laxative; but of the lime-water, few can

take more than a pint daily.

The acidulous soda-water may be taken in larger quantities, as it is more agreeable. The acidulous salt is now prepared so as to produce the water extemporaneously. It must be swallowed, however, while the salt is dissolving, as the carbonic acid very rapidly escapes.

There is a remedy celebrated in Holland, under the name of liquor lithontriptica loosii, which contains, according to an accurate analysis, calx muriata. This, professor Hufeland recommends in the follow-

ing form:

B Calcis muriatæ 3j.
Aquæ distillatæ, 3jj, ft. solutio.
Thirty drops are to be taken four times a-day, which may be increased as far as the stomach will bear.

For curing stone patients, little reliance can be placed in any lithontriptics hitherto discovered, though they may rationally be given with a confident hope of procuring an alleviation of the fits of pains attending the presence of stone in the bladder. After all, the only certain method of getting rid of the calculus is the operation. See Lithotomy.

LITHOSPERMUM. (From Ailos, a stone, and origina, seed; named from the hardness of its seed.) 1. The name of a genus of plants in the Linnæan system. Class, Pentandria. Order, Monogynia.

2. The pharmacopoial name of Milium solis. Common gromwell. The seeds of this officinal plant, Lithospermum officinale; seminibus levibus, corollis vix calycem superantibus, foliis lanceolatis, of Linnaus, were formerly supposed, from their stony hard. ness, to be efficacious in calculous and gra-

velly disorders. Little credit is given to their lithontriptic character, yet they are occasionally used as diuretic for clearing the urinary passages, and for obviating strangury, in the form of emulsion.

LITHOSPERMUM OFFICINALE. The systematic name of the officinal gromwell. See

Lithospermum.

LITHOTOMY. (Lithotomia; from Aibas, a stone, and remyw, to cut.) Cystomia. The operation of cutting into the bladder. in order to extract a stone. Several methods have been recommended for performing this operation, but there are only two which can be practised with any propriety. One is, where the operation is to be per-formed immediately above the pubes, in that part of the bladder which is not covered with peritoneum, called the high operation. The other, where it is done in the perinæum, by laying open the neck and lateral part of the bladder, so as to allow of the extraction of the stone, called the lateral operation, from the prostate gland of the neck of the bladder being laterally cut.

LITRON. (Corruptly written for vilgov.)

Nitre.

LITUS. (From lino, to anoint.) A liniment.

LIVER. naag. Hepar. A large viscus, of a deep red colour. of great size and weight, situated under the diaphragm, in the right hypochondrium, its smaller portion occupying part of the epigastric region. In the human body, the liver is divided into two principal lobes, the right of which is by far the largest. They are divided on the upper side by a broad ligament, and on the other side by a considerable depression, or fossa. Between and below these two lobes is a smaller lobe, called lobulus Spigellii. In describing this viscus, it is necessary to attend to seven principal circumstances:-its ligaments; its surfaces; its margins; its tubercles; its fissure; its sinus; and the pori biliari.

The ligaments of the liver are five in number, all arising from the peritoneum. 1. The right lateral ligament, which connects the thick right lobe with the posterior part of the displiragm. 2. The left lateral ligament, which connects the convex surface and margin of the left lobe with the diaphragm, and, in those of whom the liver is very large, with the esophagus and spleen. 3. The broad or middle supensory ligament, which passes from the diaphragm into the convex surface, and separates the right lobe of the liver from the left. It descends from above through the large fissure to the concave surface, and is then distributed over the whole liver. 4. The round ligament, which in adults consists of the umbilical vein, indurated into a ligament. . 5. The coronary ligament.

The liver has two surfaces, one superior,

which is convex and smooth, and one inferior, which is concave and has holes and depressions, to receive, not only the contiguous viscera, but the vessels running into the liver.

The margins of the liver are also two in number; the one, which is posterior and superior, is obtuse; the other, situated an-

teriorty and inferiorly, is acute.

The tubercles of the liver are likewise two in number, yiz. lobulus anonymus, and lobulus caudatus, and are found near the yena por! a.

Upon looking on the concave surface of this viscus, a considerable fissure is obvious, known by the name of the fissure of

the liver.

In order to expose the sinus, it is necessary to remove the gall-bladder, when a considerable sinus, before occupied by the

gall-bladder, will be apparent.

The blood-vessels of the liver are the hepatic artery, the vena portæ, and the cavæ hepatica, which are described under their proper names. The absorbents of the liver are very numerous. The liver has nerves from the great intercostal and eighth pair, which arise from the hepatic plexus, and proceed along with the hepatic artery and vena portæ into the substance of the liver. With regard to the substance of the liver, various opinions have been entertained. It is, however, now pretty well ascertained to be a large gland, composed of lesser glands connected together by cellular structure. The small glands which thus compose the substance of the liver are termed penicilli, from the arrangement of the arterial ramifications of the vena portæ composing each gland, resembling that of the hairs of a pencil. The chief use of this large viscus is to supply a floid, named bile, to the intestines, which is of the utmost importance in chylification. small penicilli perform this function by a specific action on the blood they contain, by which they secrete in their very minute ends the fluid termed hepatic bile; but whether they pour it into what is called a follicle, or not, is yet undecided, and is the cause of the difference of opinion respecting the substance of the liver. be secreted into a follicle, the substance is truly glandular, according to the notion of the older anatomists; but if it be secreted merely into a small vessel, called a biliary pore (whose existence can be demonstrated, corresponding to the end of each penicilli, without any intervening follicle, its substance is then, in their opinion, vascular. According to our notions in the present day, in either case, the liver is said to be glandular; for we connect to our senses the idea of a gland, when any arrangement of vessels performs the office of separating from the blood a fluid or substance different in its nature from the blood. The small vessels which receive the bile secreted by the penicilli are called pori biliarit; these converge together throughout the substance of the liver towards its under surface, and, at length, form one trunk, called ductus hepaticus, which conveys the bile into either the ductus communis choledochus, or ductus cysticus. See Gall-bludder.

Liver, acute inflammation of the. Sce

Hepatitis

Liver of sulphur. See Sulphurets. Liver wort See Hypatica terrestris. Liver wort, ash-coloured. See Lichen ci-

nereus terrestris.

Liver wort, ground. See Lichen cinereus terrestris.

Liver-wort, Iceland. See Lichen islandi-

cus.

Liver-wort, noble. See Hepatica terres-

LIVOR. (From liveo, to be black and blue.) A blackish mark on the body, from a blow. A dark circle under the eye.

Lix. (From Ass, light.) Pot-ash. Wood

ash.

LIXIVIA VITRIOLATA SULPHUREA. A sul-

phat of potash.

LIXIVIAL. Those salts are called lixivial which have been extracted by lixiviation, and these chiefly are fixed alkalis; which are therefore called lixivial salts.

LIXIVIATION. Lessive. The process employed by chymists of dissolving, by means of warm water, the saline and soluble particles of cinders, the residues of distillation and combustion, coals and neutral earths, in order to obtain those particles which are termed lixivial salts.

LIXIVIUM. (From lix, wood-ash.) The liquor in which saline and soluble particles of the residues of distillation and combus-

tion are dissolved.

LIXIVIUM SAPONARIUM. See Liquor po-

LIXIVIUM TARTARI. See Liquor carbonatis potassæ.

LOBELIA. Named in honour of Lobel, a botanist. 1. The name of a genus of plants in the Linnæan system. Class, Syngenesia

Order, Monogamia.

2. The pharmacopæial name of the blue lobelia, or cardinal flower. The root of this plant, Lobelia syphilitica, is the part directed by the Edinburgh Pharmacopæia for medicinal use; in taste it resembles tobacco, and is apt to excite vomiting. It derived the name of syphilitica from its efficacy in the cure of syphilis, as experienced by the North American Indians, who considered it as a specific in that disease, and with whom it was long an important secret, which was purchased by Sir William Johnson, and since published by

different anthors. The method of em- eight genera, viz. dysmsthesim, dysoremia, ploying this medicine is stated as follows: A decoction is made of a handful of the roots in three measures of water. this half a measure is taken in the morning fasting, and repeated in the evening; and the dose is gradually increased, till its purgative effects become too violent, when the decoction is to be intermitted for a day or two, and then renewed, until a perfect cure is effected. During the use of this medicine, a proper regimen is to be enjoined, and the ulcers are also to be frequently washed with the decoction, or, if deep and foul, to be sprinkled with the powder of the inner bark of the New Jersey tea-tree, Ceanothus Americanus. Although the plant thus used is said to cure the disease in a very short time, yet it is not found that the antisyphilitic powers of the lobelia have been confirmed in any instance of European practice.

LOBELIA SYPHILITICA. The sytematic name of the blue lobelia of the pharmaco-

pæias. See Lobelia.

LOBULUS. (Dim. of lobus, a lobe.) A small lobe.

LOBULUS ACCESSORIUS. See Lobulus anonymus.

LOBULUS ANONYMUS. Lobulus ac-The antecessorius anterior-quadratus. rior point of the right lobe of the liver. Others define it to be that space of the great lobe betwixt the fossa of the umbilical vein and gall-bladder, and extending forward from the fossa for the lodgment of the portæ, to the anterior margin of the liver.

LOBULUS CAUDATUS. Processus caudatus. A tail-like process of the liver, stretching downward from the middle of the great right lobe to the lobulus spigelii. It is behind the gall bladder and betwixt the fossa venæ portarum, and the fissure for the lodgment of the vena cava.

LOBULUS SPIGELH. Lobulus posterior. L. posticus papellatus. The lobulus spigehi is betwixt the two greater lobes, but rather belonging to the right great lobe. From its situation deep behind, and from its having a perpendicular papilla-like projection, it is called lobulus posterior, or pa-pillatus. To the left side, it has the fissure for the lodgment of the ductus venosus; on with the lower concave surface of the great lobe, by the processus caudatus, which of transversalis cervicis. the lesser curve of the stomach.

dyscinesia, apocenoses, epischeses, tumores, ectopia, and dialyses

LON

Localis membrana. The pia mater.

(From λοχευω, to bring LOCHIA, forth.) The cleansings. The serous, and for the most part green-coloured, discharge that takes place from the uterus and vagina of women, during the first four days after delivery.

LOCHIORRHŒA. (From λοχια, and ρεω, to flow.) An excessive discharge of

the lochia.

Locked jaw. See Tetanus.

Logwood. See Lignum campechense.

LOCALTIS. (From 2072%, a line; so named because the leaves resemble the head of a lance.) The herb spleenwort.

LOGANUM (From langus, long; so

named from its length.) The intestinum

Longing. A disease peculiar to the female, and only during pregnancy, and those states in which the uterine discharge

is suppressed.

LONGISSIMUS DORSI. Lumbo dorso trachalien of Dumas. This muscle, which is somewhat thicker than the sacrolumbalis, greatly resembles it, however, in its shape and extent, and arises, in common with that muscle, between it and the spine. It ascends upwards along the spine, and is inserted by small double tendons into the posterior and inferior part of all the transverse processes of the vertebræ of the back, and sometimes of the last vertebra of the neck. From its outside it sends off several bundles of fleshy fibres, interspersed with a few tendinous filaments, which are usually inserted into the lower edge of the ten uppermist ribs, not far from their tubercles. In some subjects, however, they are found inserted into a less number, and in others, though more rarely, into every one of the ribs. To-wards the upper part of this muscle is observed a broad and thin portion of fleshy fibres, which cross and intimately adhere to the fibres of the longissimus dursi. This portion arises from the upper and posterior part of the transverse processes of the five or six uppermost vertebræ of the back, by as many tendinous origins, and is usually inserted, by six tendinous the right, the fissure for the vena cava; and fleshy slips, into the transverse pro-and above, it has the great transverse fis-sure of the liver, for the lodgment of the neck. This portion is described by Winscylinder of the porta; obliquely to the low and Albinus as a distinct muscle; by right, and upwards, it has a connection the former under the name of transversalis major colli, and by the latter under that But its fibres Winslow calls one of the roots of the lobulus are so intimately connected with those of spigelin. It is received into the bosom of the longissimus dorsi, that it may very properly be considered as an appendage LOCALES. The fourth class of Cul- to the latter. The use of this muscle is to len's Nosology, which comprehends mor- extend the vertebra of the back, and to bid affections that are partial, and includes keep the trunk of the body erect; by

means of its appendage, it likewise serves to turn the neck obliquely backwards, and a little to one side.

Longissimus manus. The flexor tertii internodii pollicis.

Longissimus oculi. The obliquus ma-

jor oculi.

LONGITUDINAL SINUS. Longitudinal sinus of the dura mater. A triangular canal, proceeding in the falciform process of the dura mater, immediately under the bones of the skull, from the crista tgalli to the tentorium, where it branches into the lateral sinuses. The longitudinal sinus has a number of trabeculæ or fibres crossing it. Its use is to receive the blood from the veins of the pia mater, and convey it into the lateral sinuses, to be carried through the internal

jugulars to the heart.

LONGUS COLLI. Pre dorso cervical of Dumas. This is a pretty considerable muscle, situated close to the anterior and lateral part of the vertebræ of the neck. Its outer edge is in part covered by the rectus internus major. It arises tendinous and fleshy within the thorax, from the bodies of the three superior vertebræ of the back, laterally; from the bottom and fore-part of the transverse processes of the first and second vertebræ of the back, and of the last vertebra of the neck : and likewise from the upper and anterior points of the transverse processes of the sixth, fifth, fourth, and third vertebræ of the neck, by as many small distinct tendons; and is inserted tendinous into the fore-part of the second vertebra of the neck, near its fellow. This muscle, when it acts singly, moves the neck to one side; but, when both act, the neck is brought directly forwards.

LONICERA. The name of a genus of plants in the Linnaan system. Class, Pentandria. Order, Monogynia.

LONICERA DIERVILLA. The systematic name of a species of honey-suckle. See

Diervilla.

LONICERA PERICLIMENUM. Honey-suckle. This beautiful and common plant was formerly used in the cure of astlma, for cleansing fordid ulcers, and removing diseases of the skin, virtues it does not now appear to possess.

Looseness. Sec Diarrhaa.

LOPEX HADIX, Radix lopeziana. Radix indica lopeziana. The root of an unknown tree growing, according to some, at Goa. It is met with in pieces of different thickness, some at least of two inches diameter. The woody part is whitish, and very light; softer, more spongy, and whiter next the bark, including a denser, somewhat reddish, medullary part. The bark is rough, wrinkled, brown, soft, and, as it were, woolly, pretty thick, covered with a thin paler cuticle. Neither the woody nor corticle part has any remarkable smell.

or taste, nor any appearance of resinous matter. It appears that this medicine has been remarkably effectual in stopping colliquative diarrhœas, which had resisted the usual remedies. Those attending the last stage of consumptions were particularly relieved by its use. It seemed to act, not by an astringent power, but by a faculty of restraining and appeasing spasmodic and inordinate motions of the intestines. Dr. Gaubius, who gives this account, comparis its action to that of fimarouba, but thinks it more efficacious than this medicine.

Lopez-root. See Lopez radix.

LOPEZIANA RADIX. See Lopez radix. LOPHADIA. (From Σφος, the hinder part of the neck.) Lophia. The first vertebra of the neck.

LORDOSIS. (From ? hopgos, curved, bent.)
An affection of the spine, in which it is bent

inwards.

A kind of lute, with which vessels are coated before they are put into the fire

LORICATION. Coating. Nicholson recommends the following composition for the coating of glass vessels, to prevent their breaking when exposed to heat. Take of sand and clay, equal parts; make them into a thin paste with fresh blood, prevented from coagulating by agitation, till it is cold, and diluted with water; add to this some hair, and powdered glass; with a brush, dipped in this mixture, besmear the glass; and when this layer is dry, let the same operation be repeated twice, or oftener, till the coat applied is about one-third part of an inch in thickness.

LORIND MATRICIS. An epilepsy, or a convulsive disorder, proceeding from the uterus.

Loss of Appetite. See Anorexia.

LOTION. (Lotio; from lavo, to wash.) An external fluid application. Lotions are usually applied by wetting linen in them, and keeping it on the part affected.

LOTUS. (From λω, to desire.) 1. A tree whose fruit was said to be so delicions as to make those who tasted it to forsake all other desires: hence the proverb Λωτον εφαχον, lotum gustavi: I have tasted lotus.

2. The name of a genus of plants in the Linnwan system. Class, Diadelphia. Or-

der, Decandria.

Lousy disease. A general corruption of the humours, in consequence of which these insects are bred in ulcers, and cover the whole body.

LOVE-APPLE. The fruit of the Solanum lycopersicum of Linnæus. It is so much esteemed by the Portuguese and the Spaniards, that it is an ingredient in almost all their soups and sauces, and is deemed cooling and nutritive.

Lovenge. See Levisticum.

LOXARTHROS. (From λοξος, oblique, and αξθεον, a joint.) An obliquity of the joint, without spasm or luxation.

I waxen vein,

called also ludus paracelsi. A stony matter said to be serviceable in calculus.

LULS HEIFICA. One of the pompous names for epilepsy.

LUES NEUHODES CONVULSIVA. A mild typhus fever.

LUES VENEREA. (From )va, to dissolve, because it produces dissolution; and venerea, from Venus, because it is propagated by acts of venery.) The plague of Venus, or the venereal disease. Dr. Cullen calls it syphilis. It has also been called the venereal pestilence, or pax. Approdusius morbus. Morbus gallicus. Indicus morbus. Neapolatanas morbus. Patursa. See Syphilis and Gonorrhaa

LUJULA. (Corrupted or contracted from Allelujah, Praise the Lord; so called from its many virtues.) Acetosella, Wood-Oxalis acetosella of Linnaus. This delicate indigenous plant is totally inodorous, but has a grateful acid taste, which is more agreeable than the common sorrel, and approaches near to that of the juice of lemons, or the acid of tartar, with which it also corresponds in a great measure in its medical effects, being estcemed refrigerant, antiscorbutic, and diuretic. Its principal use, however, is to allay inordinate heat, and to quench thirst; for this purpose a pleasant whey may be formed by boiling the plant in milk. An essential salt is prepared from this plant, known by the name of Essential Salt of Lemons, and commonly used for taking ink-stains out of

LUMBAGO. (From lumbus, the loin.) A rheumatic affection of the muscles about the loins.

LUMBAGO PSOADICA. Lumbago apostematosa. Lumbago ab arthrocace. Pains in the loins from abscess,

LUMBARES ARTERIÆ. The lumbal arteries.

LUMBARES NERVI. The lumbal nerves. LUMBARES VENÆ. The lumbal nerves.

LUMBARIS EXTERNUS. See Quadratus lumborum.

LUMBARIS INTERNUS. See Psoas magnus.

LUMBAR ABSCESS. Psoas abscess. A species of arthropussis, that receives its name from the situation in which matter is found, namely, upon the side of the psoas muscle, or betwixt that and the iliacus internus. Between these muscles, there lies a quantity of loose cellular membrane, in which an inflammation often takes place, either spontaneously or from mechanical injuries. This terminates in an abscess that can procure no outlet but by a circuitous course, in which it generally produces 'irreparable mischief, without any violent symptoms occurring to alarm the patient. The abscess sometimes forms a swelling above Poupart's ligament; sometimes below it; and frequently the

matter glides under the fascia of the thigh. Oceasionally, it makes us way through the sacro-ischia ic foramen, and assumes rather the appearance of a fistula in ano. The uneasiness in the loins, and the impulse communicated to the tumour by coughing, evince that the disease arises in the lumbar region; but it must be conselsed, that we can hardly ever know the existence of the disorder, before the tumour, by presenting itself externally, leads us to such information. The lumbar abscess is sometimes connected with diseased vertebra, which, may either be a cause or effect of the collection of matter. The disease, however, is frequently unattended with this compli-

The situation of the symptoms of lumbar abscess renders this affection liable to be mistaken for some others, viz. lumbago and nephritic pains, and, towards its termination, for crural or femoral herma. The first, however, is not attended with the shivering that occurs here; and nephritic complaints are generally discoverable by attention to the state of the urine. The distinction from crural herma is more difficult. In both, a soft inclastic swelling is felt in the same situation, but in hernia, it is attended with obstructed faces, vomitting, &c. and its appearance is aiways sudden, while the lumbar tumour is preceded by various complaints before its appearance in the thigh. In a horizontal posture, the abseess also totally disappears, while the hernia does not.

Lumbar region. The loins.

LUMBRICALES MANUS. (Lumbri. cales, sc. musculus; from their resemblance to the lumbricus, or earth-worm.) Fidicinales. Flexor primi internodni digitorum manus vel perforatus lumbricales of Cowper. Anuli tendino phalangiens of Dumas. The four small fingers of the flexors of the fingers, which assist the bending of the fingers when the long flexers are in full action. They arise thin and Beshy from the outside of the tendons of the flexor profundus, a little above the lower edge of the carpal ligaments, and are inserted by long slender tendons into the outer sides of the broad tendons of the interesseal muscles, about the middle of the first joint of the fingers.

LUMBRICALES PEDIS. Planti tendino phalangien of Dumas Four ma cles like the former, that increase the flexion of the toes, and draw them inwards.

LUMBRRUS (à lubricitate; from its sipperiness.) Ascaris lumbricoides. Lumbricoides. Lumbricoides. The long round worm. A species of worm which inhabits occasionally the human intestines. It has three nipples at its head, and a triangulgr mouth in its middle. Its length is from four to twelve inches, and its thickness when twelve inches long, about that of a goose-quill. They are some-

3 N \*

times solitary, at other times very nume-

LUMBRICUS TERRESTRIS. See Earthworm.

LUMBUS VENERIS. See Millefolium.

LUNA. (So named from its resemblance in brightness to silver.) The old alchemistical name of silver.

Lunar caustic. See Nitras argenti.

LUNARE OS. One of the bones of the

LUNATICA ISCHURIA. (From luna, the moon.) A suppression of urine which re-It is noticed by Sauturns monthly.

vages, LUNG. Pulmo. The lungs are two viscera situated in the chest, by means of which we breathe. The lung, in the right cavity of the chest, is divided into three lobes, that in the left cavity into two. They hang in the chest, attached at their superior part to the neck, by means of the trachea, and are separated by the mediastinum, They are also attached to the heart, by means of the pulmonary vessels. The substance of the lungs is of four kinds, viz, vesicular, vascular, brouchial, and a parenchymatous substance. The vesicular substance is composed of the air-cells. The vascular invests those cells like a net-work. The bronchial is throughout the lungs, having the air cells at their extremities: and the spongy substance that connects the spaces between these parts is termed the parenchyma. The lungs are covered with a fine membrane, a reflexion of the pleura, called pleura pulmonalis. The internal surface of the aircells is covered with a very fine, delicate, and sensible membrane, which is continued from the larynx through the trachea and bronchia. The arteries of the lungs are the pulmonary, which circulate the blood through the air-cells to undergo a certain change, and the bronchial artery, a branch of the aorta, which carries blood to the lungs for their nourishment. The pulmonary veins return the blood that has undergone this change, by four trunks, into the left aur le of the lieart. The bronchial veins terminate in the vena azygos. The nerves of the lungs are from the eighth pair and great intercostal. The absorbents are of two orders; the superficial and deep-seated: the former are more readily detected than the latter. The glands of these viscera are called bronchial. They are muciparous, and situated about the bronchia. See Respiration.

Lung-wort, spotted. See Pulmonaria ma-

LUPIA. (From Nursew, to molest.) A genus of disease, including encysted tumours, whose contents are very thick, and sometimes solid, as meliceris, atheroma, steatoma, and ganglion.

LUPINUS. (From Aumn, grief, or dislike;

so called from its extreme bitterness.) Under this term the white lupin is directed in some pharmacopæias. The seed, the ordinary food of mankind in the days of Galen and Pliny, is now forgotten. Its farinaceous and bitter meal is occasionally exhibited to remove worms from the intestines, and made into poultices to resolve indolent tumours.

LUPINUS ALBUS. The systematic name of

the white hupin. See Lupinus.
LUPULUS. (From humn, dislike; so named from its bitterness.) Convolvulus perennis. The hop. It is the floral leaf or bractea of this plant, Humulus lupulus of Linnaus, that is dried and used in various kinds of strong beer. Hops have a bitter taste, less ungrateful than most of the other strong bitters, accompanied with some degree of warmth and aromatic bitter, and are highly intoxicating. The hopflower also exhales a considerable quantity of its narcotic power in drying; hence those who sleep in the hop-houses are with difficulty roused from their slumber. A pillar stuffed with these flowers is said to have laid our present monarch to sleep when other remedies had failed.

LUPUS. The wolf, so named from its rapacity. The cancer is also so called, because it eats away the flesh like a wolf.

LUSTRAGO. (From lustro, to expiate; so called because it was used in the ancient purifications.) Flat or base vervain.

Lute. See Lutum.

LUTEA CORPORA. See Corpora lutea.

LUTEOLA. (From lutum, mud, because it grows in muddy places, or is the colour of mud.) Struthium. Dyer's weed. Dioscorides recommends it as useful in jaundice, but it is now neglected.

LUTUM. (From Nuros, soluble.) Camentum. Mud. Lute. A composition with which chymical vessels are covered, to preserve them from the violence of the fire, and to close exactly their joinings to each other, to retain the substances which they contain when they are volatile and reduced to vapour.

LUXATION. (Luxatura; from luxo, to put out of joint.) A dislocation of a bone

from its proper cavity.

LYCHANCHE. (From AUROS, a wolf, and αγχω, to strangle. A species of quincy, in which the patient makes a noise like the howling of a wolf.

LYCHANTHROPIA. (From AUROS, a wolf, and ανθεωπος, a man.) A species of insanity, in which the patients leave their houses in the night, and wander about like wolves, in unfrequented places.

LYCHINIS. (From AUXHOS, a torch; because the ancients used its leaves rolled up for torches.) A name of several vegetable productions.

LYCOCTONUM. (From AUROS, a wolf, and arara, to slay; so called because it was

the custom of hunters to secrete it in raw flesh, for the purpose of destroying wolves.)

LYCOPERDON. (From AUROS, a wolf, and weeds, to break wind; so named because it was supposed to spring from the dung of wolves.) 1. The name of a genus of plants in the Linnaan system. Class,

Cryptogamia. Order, Fungi. 2. The pharmacopoial name of the puff-Crepitus lupi. A round or egg shaped fungus, the Lycoperdon bovista of Linuxus, when fresh, of a white colour, with a very short, or scarcely any pedicle, growing in dry pasture grounds. When young, it is sometimes covered with tubercles on the outside, and is pulpy within. By age it becomes smooth externally, and dries in-ternally, into a very fine, light, brownish dust, which is used by the common people

LYCOPERDON NOVISTA. The systematic name of the puff-ball. See Lycoperdon.

to stop hæmorrhages.

LYCOPERDON TUBER. The systematic name of the truffle. See Truffle.

LYCOPERSICUM. (From AUXOS, a wolf, and regricov, a peach; so called from its exciting a violent degree of lust.) Wolf's peach. Poisonous.

LYCOPODIUM. (From AUROS, a wolf, and muc, a foot; so called from its supposed resemblance.) 1. The name of a genus of plants in the Linnæan system. Class, Cryptogamia. Order, Musci.

2. The pharmacopæial name of the Muscus clavatus. Club moss. Wolf's claw. This plant, Lycopodium clavatum of Linnæus, affords a great quantity of pollen, which is much esteemed in some places to sprinkle on young children, to prevent, and in the curing parts which are fretting. A decoction of the herb is said to be a specific in the curc of the plica polonica.

LYCOPODIUM CLAVATUM. The systematic name of the club-moss. See Lycopo-

LYCOPODIUM SELAGO. The systematic name of the upright club-moss. See Muscus erectus.

Lycorsis. (From λυκος, a wolf, and οψις, an aspect; so called from its being of the colour of a wolf.) Echium Ægyptiacum, or wall bugloss.

LYCOPUS. (From AUROS, a wolf, and TRES, a foot; so named from its likeness.) The name of a genus of plants in the Linnxan system. Class, Diandria. Order, Monogynia. Wolf's claw, or water horehound. The lycopus europeus is astringent.

LYGISMUS. (From Augiza, to distort.) A dislocation.

(From avyilar, to bend; so called from its flexibility.) The agnus castus.

LYMPH. Lympha. The liquid contained in the lymphatic vessels. It has a fatuous smell, no taste, and is of a crystalline colour. Its specific gravity is greater than water; in consistence, it is thin and

somewhat plastic. The quantity in the human body appears to be very great, as the system of the lymphatic vessels forms no small part of it. Its constituent principles appear to be gelatinous albuminous water. The lymphatic vessels absorb this water from the tela cellulosa of the whole body, from all the viscera and the cavities of the viscera; and convey it to the thoracic duct, where it is mixed with the clivle.

The use of the lymph is to turn the superfluous nutritious jelly from every part, and to mix it with the chyle in the thoracic duct, there to be further converted into the nature of the animal; and lastly, it has mixed with it the superfluous aqueous vapour, which is expired into the cavity of the cranium, thorax, and abdomen. LYMPHATIC GLANDS.

Glandulæ

lymphatica. See Conglobate glands.
LYMPHATICS. Absorbent vessels, that carry a transparent fluid, or lymph. They are small and transparent, and originate in every part of the body. With the lacteal vessels of the intestines, they form what is termed the absorbent system. Their termination is in the thoracic duct. Absorbent vessels, Lacteals, and Thoracic duct.

Lymphatics of the head and neck .- Absorbents are found on the scalp and about the viscera of the neck, which unitc into a considerable branch, that accompanies the jugular vein. Absorbents have not been detected in the human brain: yet there can be no doubt of there being such vessels: it is probable that they pass out of the cranium through the canalis caroticus and foramen lacerum in basi cranii, on each side, and join the above jugular branch, which passes through some glands as it proceeds into the chest to the angle of the subclavian and jugular veins.

The absorbents, from the right side of the head and neck, and from the right arm. do not run across the neck, to unite with the great trunk of the system; they have an equal opportunity of dropping their contents into the angle betwixt the right subclavian and the jugular vein. These vessels then uniting, form a trunk, which is little more than an inch, nay, sometimes not a quarter of an inch, in length, but which has nearly as great a diameter as the proper trunk of the left side.

This vessel lies upon the right subclavian vein, and receives a very considerable number of lymphatic vessels; not only does it receive the lymphatics from the right side of the head, thyroid gland, neck, &c. and the lymphatics of the arm, but it receives also those from the right side of the thorax and diaphragm, from the lungs of this side, and from the parts supplied by the mammary artery. Both in this and in the great trunk there are many valves.

Lymphatics of the upper extremities .-

The absorbents of the upper extremities are divided into superficial and deep-6" ed. The superficial absorbents ascend under the skin in every direction to the wrist, from whence a branch proceeds upon the posterior surface of the fore-arm to the head of the radius, over the internal condyle of the hamerus, up to the axilla, receiving several branches as it proceeds. Another branch proceeds from the wrist along the anterior part of the fore-arm, and forms a net work, with a branch coming over the ulna from the posterior part, and ascends on the inside of the humerus to the glands of the axilia. The deep seated absorbents accompany the larger blood-vessels, and pass through two grands about the middle of the humerus, and ascend to the glands of the axilla. The superficial and deen-scated absorbents having passed through the axillary glands, form two trunks, which unite into one, to be inserted with the jugular absorbents into the thoracic duct, at the angle formed by the union of the subclavian wit the jugular vein.

Lymphatics of the inferior extremities .-These are also superficial and deep seated. The superficial ones lie between the skin and massles. Those of the toes and foot form a branch, which ascends upon the back of the foot, over the tendon of the cruzus anticus, forms with other branches a plexus above the ancles, then proceeds along the tibia over the knee, sometimes passes through a gland, and proceeds up the inside of the thigh, to the subingumal glands. The deep-seated absorbents fullow the course of the arteries, and accompany the femoral artery, in which course they pass through some glands in the leg and above the knee, and then proceed to some deep-seated subinguinal glands. The absorbents from about the external parts of the pubis, as the penis, permeum, and from the external parts of the petvis, in general proceed to the inguinal glands. The subinguinal and inguinal glands send for h several branches, which pass through the abdominal ring into the cavity of the abdomen.

Lymbiatics of the abdominal and thoracic viscera, - The absorbents of the lower extremities accompany the external diac artery, where they are joined by many branches from the uterus, urinary bladder, spermatic chord, and some branches accomparrying the internal iliae arrery; they the a cend to he sacroin, where they form a plexus, which proceeds over the psoas muscles, and, meeting with the lacteals of the mesentery, with the thoracic duct, or trank of the absorbents, which is of a serpentine form, about the size of a crowqual, and cuns up the dorsal vertebræ, through he posterior opening of the diaphragm, octween the aorta and vena azygos, to the angle formed by the union of

the subclavian and jugular veins. In this course it receives: -the absorbents of the kidneys, which are superficial and deepseated, and unite as they proceed towards the thoracic duct: and the absorbents of the spleen, which are upon its peritoneal coat, and unite with those of the pancreas :- a branch from a plexus of vessels passing above and below the duodenum, formed by the absorbents of the stomuch. which come from the lesser and greater curvature, and are united about the pylorus with those of the pancreas and liver, which converge from the extern . I surface and internal parts towards the portæ of the liver, and also by several branches from the gall-bladder.

Use of Lynphatics.—The office of these vessels is to take up substances which are applied to their mouths; thus the vapour of circumscribed cavities, and of the cells of the cellular membrane, are removed by the lymphatics of those parts; and thus mercury and other substances are taken into the system when rubbed on the skin.

The principle by which this absorption takes place, is a power inherent in the mouths of absorbing vessels, a vis insita, dependent on the high degree of irritability of their internal membrane, by which the vessels contract and propel the fluid forwards. Hence the use of this function appears to be of the utmost importance, viz. to supply the blood with chyle; to remove the superfluous vapour of circumscribed cavities, otherwise dropsies, as hydrocephalus, hydrothorax, hydrocordis, ascites, hydrocele, &c. would constantly be taking place: to remove the superflu-ous vapour from the cells of the cellular membrane dispersed throughout every part the body, that anasarca may not take place: to remove the hard and soft parts of the body, and to convey into the system medicines which are applied to the surface of the body.

LYPOMA. See Lipoma. LYRA. (From λυgα, a lyre, or musical instrument.) Psalterium. The triangular medullary space between the posterior crura of the formx of the cerebrum, which is marked with prominent medullary fibres that give the appearance of a lyre.

LYRUS. (From lyra, the lyre; so called because its leaves are divided like the strings of a lyre.) The doronicum Germani-

cum, or German leopard's-bane.

Lysievia. (From Nue, to loosen, and your, a member.) The relaxation of limbs. LYSIMACHIA. (From Lysimachus,

who first discovered it.) The name of a genus of plan's in the Linnaan system. Cass, Pentandria. Order, Monogynia. LYSIMACHIA NUMMULARIA. The syste-

matic name of the money-wort. See Nummularia. The herb,

LYSIMACHIA PURPUREA.

root, and flowers of this plant, Lythrum salicaria of Lumwus, possess a considerable degree of astringency, and are used medicinally in the cure of diarrheas and dysenteries, fluor albus, and hamoptysis.

LYSSODECTUS. (From Awsta, canine madness, and fancupi, to bite.) One who is mad in consequence of having been bit-

ten by a mad annual.

LYTHRUM. (From 2.08gov, blood; so

called from its resemblance in colour, and Salicaria, from saiix, a willow; from the resemblance of its leaves to those of a willow.) The name of a genus of plants in the Linnean system. Class, Dodeandria. Order, Digynia.

LYTHRUM SALICARIA. The systematic name of the common or purple willow-

herb. See Lysimachia purpurea.

## M.

M. This letter has two significations: when herbs, flowers, chips, or such-like substances, are ordered in a prescription, and M. follows them, it signifies manipulus, a handful; and when any quantity of other ingredients is directed, it is a contraction of misce; thus, m. f. mist. signifies mix and make a mixture.

MACANDON. (Indian.) A tree growing in Malabar, whose fruit is roasted and eaten as a curc for dysenteries and relief in cholera morbus, and other complaints.

MACAPATLI. Sarsaparilla.

MACANOCOTLIFERA. The name of a tree in the West Indies, whose fruit is sweet and laxative. A decoction of the bark of this tree cures the itch, and the powder thereof heals ulcers.

Macedonian parsley. See Petroselinum

Macedonicum.

MACEDONISIUM SEMEN. The seeds of the Smyrnium olusatrum, said to possess bitterish, aromatic, and carminative virtues.

Macen. (From masa, Heb.) Grecian macer, or mace. The root which is imported from Barbary by this name is supposed to be the simarouba, and is said to

be antidysenteric.

MACERATION. (From macero, to soften by water.) In a pharmaceutical sense, this term implies an infusion either with or without heat, wherein the ingredients are intended to be almost wholly dissolved, in order to extract their virtues.

MACERONA. The Smyrnium olusatrum or herh Alexander.

MACHÆHIA. The persicaria, or peachkernels.

MACHERION. Macheris. The ampu-

tating-knife.

MACHAON. The proper name of an antient physician, said to be one of the sons of Asculapius; whence some authors have functed to dignify their own inventions with his name, as particularly a collyrium, described by Scribonius, intitled, Asclepias Machaonis; and hence, also, medicine in general is by some called Ars Machaonia.

MACHINAMENTUM ARISTIONIS. A machine for reducing dislocation.

MACHINULE. A word sometimes used by physical writers to express those little compositions, which are parts of stone. It is a sort of rocky marle.

Macia. The anagallis.

MACIES. A wasting of the body. See Atrophy and Tabes.

MACIS. Mace. The middle bark of the nutmeg. A thick, tough, reticulated unctuous membrane, of a lively, reddish, yellow colour, approaching to that of saffron, which envelopes the shell of the nutmeg. See Nux moschata. The mace, when fresh, is of a blood-red colour, and acquires its yellow hue in drying. It is dried in the sun, upon hurdles fixed above one another, and then, it is said, sprinkled with seawater, to prevent its crumbling in carrying. It has a pleasant aromatic smell, and a warm, bitterish, moderately pungent taste. It is in common use as a grateful spice, and appears to be in its general qualities nearly similar to the nutrneg. The principal difference consists in the mace being much warmer, more bitter, less unctuous, and sitting easier on weak stomachs.

Mace possesses qualities similar to those of nutmeg, but is less astringent, and its oil is supposed to be more volatile and acrid.

MACRE. The macer.

MACROPHYSOCEPHALUS. (From mangor, long, quois, nature, and κεφαλη, the head.) One who has a head unnaturally long and large. This word, according to Turton, is only used by Ambrose Parey.

MACROPIPER. (From μακεςς, long, and πιπεςις, pepper.) See Piper longum.

MACROPNEA. (From μακεςς, long, and

(From maxeos, long, and TYEE, to breathe.) A difficulty of breathing, where the inspirations are at long intervals.

MACULA. A spot. A permanent dis-colouration of some portion of the skin, often with a change of its texture, but not

connected with any disorder of the constitution.

MACULE ALBE. White specks on the

MACULE HEPATICE. Hepatic, or livercoloured spots on the skin.

Shingles, or crysipe-MACULE LATE.

MACULE OCULORUM. Cataracts; white

specks on the eye. MACULE PESTILENTES. Petechial, or

purple spots. MACULE VENEREE. The vencreal erup-

MACULE VOLATICE. Any transitory eruption.

MAD-APPLES. The oblong egg-shaped fruit of the Solanum melongena of Linnæus. They are often boiled, in their native places, in soups and sauces, the same as the love-apple; are accounted very nutritive, and are much sought after by the votarics of Venus.

MADAROSIS. (From masos, bald, without hair.) A defect or loss of eye-brows. or eye-lashes, causing a disagreeable deformity, and painful sensation of the eyes in a strong light.

Madder. See Rubia. Madness. See Melancholia, Insania, and Mania.

Madness, Canine. See Hydrophobia. Moisture. A sweating. See

Ephidrosis. Magdaleon. (From μασσω, to knead.) A mass of plaster, or other composition,

reduced to a cylindrical form. MAGELLANICANUS CORTEX. The Win-

teranus cortex, nearly allied in its properties to canella alba

(From magister, a mas-MAGISTERY. ter.) The ancient chymists used this word to signify a peculiar and secret method of preparing any medicine, as it were, by a masterly process. A subtle preparation, as a precipitate or solution by menstruum.

MAGISTRALIA. (From magister, a master.) Applied, by way of eminence, to such medicines as are extemporancous, or

in common use.

MAGISTRANTIA. (From magistro, to rule; so called by way of eminence, as exceeding all others in virtue.) See Imperatoria.

MAGMA. (From μασσω, to blend together ) Ecpiesma. A thick ointment. The faces of an ointment after the thinner parts are strained off. A confection,

MAGNES. (From Magnes, its inven-The magnet, or load-stone. A muddy iron ore, in which the iron is modified in such a manner as to afford a passage to a fluid called the magnetic fluid. The magnct exhibits certain phenomena; it is known by its property of attracting steel filings, and is found in Auvergne, in Biscay, in Spain, in Sweden, and Siberia.

MAGNES ARSENICALIS. Arsenical magnet. It is a composition of equal parts of antimony, sulphur, and arsenic, mixed and melted together, so as to become a glassy

MAGNES EPILEPSIE. The native cinna-

MAGNESIA. 1. The ancient chymists gave this name to such substances as they conceived to have the power of attracting any principle from the air. Thus an earth which, on being exposed to the air, increased in weight, and yielded vitriol, they called magnesia vitriolata: and later chymists observing, in their process, that a nitrous acid was separated, and an earth left behind, supposing it had attracted the acid, called it magnesia nitri, which, from its colour, soon obtained the name of magnesia alba.

2. An earth not found pure in nature, but obtained by art from some of its combinations. It gives a peculiar character to the substances of which it forms a part. The stones which contain magnesia in a considerable quantity have generally a smooth and unctuous feel, a greenish cast, a fibrous or striated texture, and a silky lustre. Among them we may mention talc, steatite, serpentine, chlorite, asbestos, actynolite, jade, or nephritic stone, baikalite, boracite, &c. It is likewise found neutralized with various acids. It has been discovered by Vauquelin in seve-

ral sca-plants.

Properties.-Pure magnesia does not form with water an adhesive ductile mass. It is in the form of a very white spongy powder, soft to the touch, and per-fectly tasteless. It is very slightly soluble in water. It absorbs carbonic acid gradually from the atmosphere. It changes very delicate blue vegetable colours to green. Its attraction to the acids is weaker than those of the alkalies. Its salts are partially decomposed by ammonia, one part of the magnesia being precipitated, and the other forming a triple compound. Its specific gravity is about 2.3. It is infusible even by the most intense heat; but when mixed with some of the other earths it becomes fusible. It combines with sulphur. It does not unite to phosphorus or carbon. It is not dissolved by alkalies in the humid way. When heated strongly, it becomes phosphorescent. With the dense acids it becomes ignited. With all the acids it forms salts of a bitter taste, mostly very soluble.

Method of obtaining Magnesia. The usual method of procuring magnesia is, to precipitate it from sulphate of magnesia by

means of an alkali.

To effect this, dissolve any quantity of sulphate of magnesia in a large quantity of distilled water, and add to it gradually a solution of perfectly pure carbonate of pot-

MAI

463

ash, or soda, till no more precipitate en- cinally as an absorbent, antacid, and purgasues. Then collect the precipitate on a cloth, and boil it repeatedly in a large quantity of distilled water, till this fluid passes perfectly tasteless. It is then to be dried, and exposed in a crucible to a red heat, till a sample of it, when cold, does not occasion theleast effervescence with acids.

In this process, a double decomposition takes place, the sulphuric acid of the sulphate of magnesia combines with the alkali, and forms sulphate of potash; and the carbonic acid of the alkali joins to the disengaged magnesia, and forms carbonate of magnesia; the latter is precipitated, and the sulphate of potash remains in solution. On exposing the carbonate of magnesia to heat, the acid is expelled, and the magnesia is left behind in a pure state. The magnesia of the present London Pharmacopœia was formerly called Magensia calcinata; usta; pura. It is directed to be made thus: - " Take of carbonate of magnesia, four ounces; burn it in a very strong fire, for two hours, or until acetic acid being dropped in extricates no bubbles of gas." It is given as an absorbent antacid, and eccoprotic, in cardialgia, spasms, convulsions, and tormina of the bowels of infants; pyrosis, flatulencies, and other diseases of the primæ viæ; obstipation, leucorrhœa, rickets, scrofula, crusta lactea, and podagra. The dose is from half a drachm to a drachin.

Magnesia calcinata, See Magnesia.

Magnesia opalina, In making the

hepar antimonii, some add, to the antimony and nitre, decrepitated sal-ammoniae, and thus make the opalin. It is a weaker emetic than the liver of antimony.

MAGNESIA VITRIOLATA. See Sulphas mag-

MAGNESIA USTA. See Magnesia.

MAGNESLE CARBONAS. The London College direct it to be made as follows: Take of the sulphate of magnesia, subcarbonate of magnesia, of each a pound; water, three gallons. Dissolve the subcarbonate of potash in three pints of water, and strain. Dissolve also the sulphate of magnesia, separately, in five pints of the water, and strain; then add the rest of the water to the rest of the solution, apply heat, and when it boils pour in the former solution, stirring them well together; next, strain through a linen cloth; lastly, wash the powder repeatedly with boiling water, and dry it upon bibulous paper, in a heat of 200°. It is in form of very fine powder. considerably resembling flour in its appearance and feel; it has no sensible taste on the tongue; it gives a faint greenish colour the tincture of violets, and converts turnsole to a blue. It is employed medi-

tive, in doses from half a drachm to two drachms. See Carbonas magnesiæ.

MAGNISIÆ SULPHAS. See Sulphas

magnesi.e.

MAGNET. See Magnes.

MAGNETISM. The property which iron possesses of attracting or repelling other iron according to circumstances.

MAGNETISM, ANIMAL. A sympathy lately supposed, by some persons, to exist between the magnet and the human body; by means of which the former became capable of curing many diseases in an unknown way, somewhat resembling the performances of the old magicians. Animal magnetism is now entirely exploded.

MAGNUM DEI BONUM. So Dr. Mead calls

the Pernyian bark.

The third bone of MAGNUM OS. the lower row of bones of the carpus, reckoning from the thumb towards the little finger.

MAGNUS MORBUS. The great disease.

So Hippocrates ealls the epilepsy.

MAGYDARIS. The root of the herb lasserwort.

MAHAGONI. The systematic name of the tree the wood of which bears this name, and is so well known, is the Swietenia mahogoni of Linnxus. Its bark, when dried, has an adstringent bitter taste, similar to that of Peruvian bark, but stronger, for which it appears it may be substitued in the cure of fevers, and other diseases.

Manales. A species of Prunus. MAHMOUDY. Scammonium. Maidenhair. See Adianthum.

MAIDENHAIR, CANADA. Adianthum Canadense. This is the Adianthum pedatum of Linnaus. It is in common use in France, for the same purposes as the common adianthum is in this country, and appears to be far superior to it.

Maidenhair, English. See Adianthum. MAIDENHAIR-TREE. Ginkgo. Ginan Itsio. In China and Japan, where this tree grows, the fruit acquires the size of a damask plumb, and contains a kernel resembling that of our apricot. These kernels always make part of the desert at all public feasts and entertainments. They are said to promote digestion, and to cleanse the stomach and bowels.

MAJANTHEMUM. See Lilium convallium. MAIL-ANSCHI. A species of rhamnus growing in Malabar. A decotion of its root is recommended against the gout; and a decoction of its leaves against the jaun-

MAIL-CLOU. A Malabar tree, from whose bruised leaves and bark is prepared an apozem against the after pains of women in childbed, and for promoting the lochia.

MAIL-CLOU-KATOU. This is larger than

the above species. It is evergreen and

MAJORANA. (Quod mense Maiofloreat, because it flowers in May.) Sweet marjoram. Origanum majorana of Linaxus:-foliis ovatis obtusis, spicis subrotundis compactis pubescent bus. This plant has been long cultivated in our gardens, and is in frequent use for culinary purposes. The leaves and tops have a pleasant smell, and a moderately warm, aromatic, bitterish taste. They yield their virtues to aqueous and spirituous liquors, by infusion, and to water in distillation, affording a considerable quantity of essential oil. The medicinal qualities of the plant are similar to those of the wild plant (see Origanum;) but being much more fragrant, it is thought to be more cephalic, and better adapted to those complaints known by the name of nervous; and may therefore be employed with the same intentions as lavender. It was directed in the pulvis sternututorius, by both pharmacopæias, with a view to the agreeable odour which it diffuses to the asarabacca, rather than to its errhine power, which is very inconsiderable; but is now wholly omitted in the Pharm. Lond. In its recent state, it is said to have been successfully applied to schirrous tumours of the breast.

See Marum syri-MAJORANA SYRIACA.

acum.

MALA. (From malus, an apple; so called from its roundness.) A prominent part of the cheek.

MALA ASSYRIA. The citron.

MALA ÆTHIOPICA. A species of Lico-

MALA AURANTIA. See Aurantium his-

MALA COTONEA. The quince.

MALA INSANA NIGRA. The fruit of the black fruited night-shade. See Melongena.

MALABAR PLUM. This fruit, which is the produce of the Eugenia jumbos, smells, when ripe, like roses. On the coast of Malabar, where the trees grow plentifully, these plums are in great esteem. They are not only eaten fresh off the trees, but are preserved in sugar, in order to have them eatable all the year. Of the flowers, a conserve is prepared, which is used medicinally, as a mild adstringent.

MALABATHRI OLEUM. Oil of cassia

lignea.

(Μαλαδαθεον: from MALABATHRUM. Malabar, in India, whence it was brought, and betre, a leaf, Ind.) The leaf of the tree whose bark is called cassia. See Cassia lignea.

махававеоч. MALABATRINUM. (From malabathrum.) Ointment of malabathrum. It is compounded of myrrh, spikenard, malabathrum, and many other aromatic ingrechents.

Malacu bean. See Anucardium orientale,

MALACA RADIX. The root of the sagittaria alexipharmaca.

MALACHE. (From μαλακος, soft; called from the softness of its leaf.) The mailow.

MALACHITE. (From μαλαχη, the mallow; from its resemblance in colour to the m llow.) A species of copper ore found in Siberia.

MALACIA. (From μαλαχίον, a ravenous fish.) Pica, or depraved appetite, when such things are coveted as are not proper for food.

MALACOSTEON. (From manages, soft, and oseov, a bone.) Molities ossium, or softness of the bones,

MALACTICA. (From μαλασσω, to soften.)

Emollient medicines.

MALÆ OS. (From malus, so called from its roundness.) The cheek-bone. See Jugale os.

MALAGFUETTA. Malagnetta. Grains of

Paradise.

MALAGMA. (From μαλασσα, to soften.) Baos. It is synonymous with Cataplasma, from the frequency of making cataplasin to soften; but formerly malagmas were made of many other ingredients.

MALAMIRIS. A species of Piper.

MALARUM OSSA. The cheek-bones. See Jugale os.

MALATS. Salts formed by the union of the malic acid, or acid of apples, with different bases; thus malat of copper, malat of lead, &c.

Male. The arm-pit. Male fern. See Filix. Male orchis. See Satyrion. Male speedwell. See Veronica.

MALIC ACID. Acidum malicum. This acid is obtained by saturating the juice of apples with alkali, and pouring in the acetous solution of lead, until it occasions no more precipitate. The precipitate is then to be edulcorated, and sulphuric acid poured on it, until the liquor has acquired a fresh acid taste, without any mixture of sweetness. The whole is then to be filtered, to separate the sulphate of lead. The filtered liquor is the malic acid, which is very pure, remains always in a fluid state, and cannot be rendered concrete. The union of this acid with different bas s constitutes what are called malats.

MALIGNANT. Malignus. A term which may be applied to any disease, whose symptoms are so aggravated as to threaten destruction of the patient. It is frequently used to signify a dangerous epidemic.

Malignant fever. See Typhus putrida. Malignant sore throat. See Cynanche maligna.

MALIS. A disease of the skin, produced by an insect lodging underneath. It is very common in Persia, where the disease is produced by the worm called Gordius medinensis, or Dracunculis persious; in America, by the Pulex; and it is sometimes

Produced in Europe by the Pediculus.

Mallam-roddall. The name of a tree Malabar, the root, bark, leaves, and fruit of which are estcemed, as a specific,

in the epilepsy.

MALLEABILITY. (Malleabilitas; from malleus, a hanner.) The property which several metals possess of being extended under the hammer into thin plates, without cracking. The thin leaves of silver and gold are the best examples of malleability.

MALLEAMOTHE. Pavette. Pavate. Erysi-pelas curans arbor A shrub which grows The feaves, boiled in palm in Malabar oil, cure the impetigo; the root, powdered, and mixed with ginger, is diuretic.

MALLEI ANTERIOR. See Lasator tumpani.

MALLEI EXTERNUS. See Laxator tympani.

MALLEI INTERNUS. See Tensor tumpuni

MALLEOLUS. (Dim. of malleus, a mallet; so called from its supposed resemblance to a mallet.) The ankle, distinguished into external and internal, or

malleolus & ternus and internus.

MALLEUS. (Quusi molleus; from mollio, to soften; so called from its likeness to a little hammer.) A bone of the internal ear is so termed. It is distinguished into a head, neck, and manubrium. The head is round, and encrusted with a thin cartilage, and annexed to another bone of the ear, the incus, by ginglymus. Its neck is narrow, and situated between the head and manubrium, or handle; from which a long slender process arises, adheres to a furrow in the auditory canal, and is continued as far as the fissure in the articular cavity of the temporal bone. The manubrium is terminated by an enlarged extremity, and connected to the membrana tympani by a short conoid pro-

Mallow, common. See Malva.

Mallow, round-leaved. See Malva rotundifolia.

Mallow, vervain. See Malva alcea.

MALOGRANATUM. (From malum, an apple, and granum, a grain; so named from its grain-like seeds.) The pomegranate.

MALPHIGIA GLABRA. (So named in hour of Malphigius.) The systematic nour of Malphigius.) name of a tree which affords an esculent

cherry.

MALTHA. (From μαλασσω, to soften.) Malthacodes. A medicine softened and tempered with wax.

MALTHACTICA (From μαλθακίζω, to soften.) Emollient medicines.

MALTREORUM. Common salt.

MALUM. 1. A disease. 2. An apple. S. In a strict sense, it is the disease called Procidentia oculi; it is when the eyes exceed the bounds of the eye-lids.

MALUM MORTUUM A disease that appears in the form of a pustule, which soon forms a dry, brown, hard, and broad crust. It is seidom attended with pain, and remains fixed for a long time before it can be detached. It is mostly observed on the tibia and os coccygis, and sometimes the face.

MALVA. (Malva, quasi molva; from mollis, soft; named from the softness of its leaves.) 1. The name of a genus of plants in the Linnaan system. Class, Mo-

nadelphia. Order, Polyandria.

2. The pharmacopæial name of the common mallow. Mulva vulgaris. Malva sylvestres of Lin æus :- caule erecto herbaceo, foliis septemlobatis acutis, pedunculis petiolisque pilosis. This indigenous plant has a strong affinity to the althea, both in a hotanical and a medical respect. See Althaa. The leaves and flowers are principally used in fomentations, cataplasms, and emollient enemas. The internal use of the leaves seems to be wholly superseded by the radix althex.

MALVA ALCEA. The vervain mallow. The flowers of this plant are used medi-

cinally in some countries.

MALVA ARBOREA. The mallow-tree. This beautiful tree is the alcea rosacea of Linnaus. The flowers are said to possess adstringent and mucilaginous virtues. They are seldom used medicinally.

MALVA HOTUNDIFOLIA. Round-leaved mallow. The whole herb and root possess similar virtues to, and may be substituted for, the common mallow. See Malva.

Malva sylvestris. The systematic

name of the common mallow. See Mal-

MALVA VERBENACEA. Alcea Alcea. vulgaris major. Vervain mallow. plant is distinguished from the common mallow, by its leaves being jagged, or cut in about the edges. It agrees in virtues with the other mallows, but it is least mucilaginous of any.

MALVAVISCUS. (From malva, the mallow, and viscus, glue; so named from its viscidity.) The marsh-mallow. See Al-

than officinalis.

MALVA VULGARIS. See Malva.
MALVERN WATER. The village of Great Malvern has, for many years, been celebrated for a spring of remarkable purity, which has acquired the name of the holy well, from the reputed sanctity of its waters, and the real and extensive benefit long derived in various cases from its

The holy-well water, when first drawn, appears quite clear and pellucid, and does not become sensibly turbid on standing. It possesses somewhat of an agreeable pungency to the taste; but this is not considerable. In other respects it does not differ in taste from pure good water.

The contents of Malvern holy-well are;—some carbonic acid, which is, in an uncombined state, capable of acting upon iron, and of giving a little taste to the water; but the exact quantity of which has not been ascertained:—a very small portion of earth, either lime or magnesia, united with the carbonic and marine acids;—perhaps a little neutral alkaline salt, and a very large proportion of water:—for we may add, that, the carbonic acid perhaps excepted, the foreign matter is less than that of any spring-water which we use. No iron, or metal of any kind, is found in it, though there are chalybeates in the neighbourhood.

It is singular, that, notwithstanding its apparent purity, this water is said not to keep vell, and soon acquires a fætid smell,

by standing in open vessels.

Malvern water, like many others, was at first only employed as an external application; and this, indeed, is still its principal use, though it is extended, with some advantage, to a few internal diseases. It has been found highly efficacious in painful and deep ulcerations, the consequence of a scrophulous habit of body, and which are atways attended with much local irritation, and often general fever. Applied to the sorc, it moderates the profuseness of the discharge, corrects the fetor, which so peculiarly marks a caries of the bone, promotes the granulating process, and a salutary exfoliation of the carious part; and by a long perseverance in this course, very dangerous and obstinate cases have at last Inflammation of the eye. been cured. especially the ophthalmia, which is so troublesome in scrophulous habits, often yields to this simple application, and we find that, for a great number of years, persons afflicted with sore eyes have been in the habit of resorting to Malvern holy-well. Another order of external diseases, for which this water is greatly celebrated, is cutaneous eruptions; even those obstinate cases of dry desquamations, that frequently follow a sudden application of cold in irritable habits, are often cured by this reme-Where the skin is hot and dry, it remarkably relieves the intolerable itching of herpetic disorders, and renders the surface of the body more cool and perspirable. It appears, however, from a nice observation of Dr. Wall, that this method of treatment is not so successful in the entaneous eruptions of very lax leucophlegmatic habits, where the extremities are cold and the circulation languid; but that it succeeds best where there is unusual irritation of the skin, and where it is apt to break in painful fissures, that once out a watery acrid lymph. On the first application of this water to an inflamed surface, it will often for a time increase the pain and irritation, but these effects go off in a

few days.

The great benefit arising from using Malvern waters, as an external remedy, in diseases of the skin, and surface of the body, have led to its employment in some internal disorders, and often with considerable advantage. Of these, the most important are, painful affections of the kidneys and bladder, attended with the diseharge of bloody, purulent, or foctul urine; the heetic fever, produced by scropintious ulceration of the lungs, or very extensive and irritating sores on the surface of the body; and also fistulas of long standing, that have been neglected, and have become constant and troublesome sores.

The Malvern water is in general a perfectly safe application, and may be used with the utmost freedom, both as an external dressing for sores and as a common

drink.

The internal use of Malvern waters is sometimes attended at first with a slight nausea, and, not unfrequently, for the first day or two, it occasions some degree of drowsiness, vertigo, or slight pain of the head, which comes on a few minutes after drinking it. These symptoms go off spontaneously, after a few days, or may readily be removed by a mild purgative. effects of this water on the bowels are not at all constant; frequently it purges briskly for a few days, but it is not uncommon for the body to be rendered costive by its use, especially, as Dr. Will observes, with those who are accustomed to malt liquors. In all eases it decidedly increases the flow of urine, and the general health of the patient. The duration of a course of Malvern waters must vary very considerably, on account of the different kinds of disease for which this spring is resorted to.

Mamel. The mammoe, momin, or toddy tree. This tree is found in different parts of the West Indies, but those on the Island of Hispaniola are the best. From incisions made in the branches, a copious discharge of pellucid liquor is obtained, which is called momin, or toddy wine; it must be drank very sparingly, because of its very diuretic quality. It is esteemed as an effectual preservative from the stone, as also a solvent of it when generated.

There are two species.

Mamille. (Dim. mamma, the breast.) The breasts of men are so termed. It is likewise applied sometimes to the nipole.

Mamina. It is said, by Paulus Ægineta, to be the root of a plant which is of a detergent quality. Some think it is the root of the doronicum; but what it really is cannot be ascertained. MAMMA. See Breast.

MIMMARY ARTERIES. Ateria mammillares. The internal mainmary artery is a branch of the subclavian, and gives off the mediastinal, thymai, and pericardiac arte ries. The external mammary is a branch of the axillary artery.

MAMMARY VEINS. Venæ mammillares. These vessels accompany the arteries, and evacuate their blood into the subclavian

MAMMEA AMERICANA. The systematic name of the tree on which the mammee

fruit grows. See Mammee.

MANNEE. A dolocous fruit, the produce of the Mammea Americana of Linnaus. They have a very grateful flavour when ripe, and are much cultivated in Jam ica, where they are generally sold in the markets for one of the best fruits of the

MAN. Homo. Man is compounded of solids, fluids, a vital principle, and, what distinguishes him from every other animal,

1. The solids are divided into hard and soft, which analysis demonstrates to be formed of earthy particles, connected together by an intermediate gluten. The hard parts are the bones and cartilages. The soft parts, muscles, nerves, the viscera, and every other part except the fluids. See Bones, Cartilages, Ligaments, Muscles, Arteries, Veins, Nerves, Lymphatics, Viscera, &c.

II. The fluids are very various. See Fluids. Anatomy demonstrates the structure of the various parts of which the human body consists. Chymistry has, of late, made great progress towards ascertaining its principles and elements, which are as

follows :

The constituent principles of man are, 1. The water, which constitutes the greatest part of the humours, and is the vehicle of the other principles. 2. The animal gas, which consists of carbonated hydrogen, and is found, not only in the blood, but in all the other fluids. 3. The inflammable gas, emitted from the large intestines, in flatu. 4. The animal gluten, which consists of carbon and azote, and forms the fibres of the solid parts; the caseous portion of the milk; and the cruor of the blood. 5. The albumen, present in the serum of the blood. 6. The jelly, found in the serum of the blood; lymph of the lymphatic vessels, and other fluids; and the interstices of all the fibres. 7. The cruor, which is the animal gluten impregnated with oxydated iron. 8. The mucus, which lubricates the prima via; the acreal surfaces of the lungs; the parts of generation, and the urinary passages. 9. The animal od, which fills the cells of the adipose membrane. 10. The resin, found in

the bile. 11. The cebacic acid, which is present in animal oil. 12. The phosphoric acid, which enters into the composition of the animal earth of the bones, and the phosphorated salts of the urine. 13. The lactic acid, in the sugar of the serum of the milk. 14. The sugar, latent in the serum of the nack. 15. The animal earth, which is a phosphorated calx, and not only forms the greatest part of the bones, but also is found in the fibres of the soft pares, and ma all the fluids. 16. Phosphorated volatile alk di; and 17. Phosphorated soda, b n of which are detected in the uring, 18, Culinary salt, obtained from the urine, gastric juice, senien, and . 'er humours.

The clementary principles of our body. hitherto known, are, 1. Azot, an element which, combined with hydrogen, constitutes volatile alkali; with the matter of heat, azotic air; with carbon, the gluten of animal fibres. Azot is the primary element of the animal body, for it may be extracted from almost every part of the animal, by means of the nitrous acid, this having a greater affinity with the elements than the azot itself. The mucus, jelly, membranes, tendons, ligaments, and cartilages, afford it in a less degree by means of the nitrous acid. The lymph, serum of the blood, the water of hydropic patients, the liquor amnii, and cheese give out more. The greatest quantity of azot is obtained from the coagulable lymph of the blood, and from muscle. The flesh of young animals contains less than that of old; and it is in greater quantity in sarcophagous, than in the flesh of phytophagous animals and fish. It is not probable that the azot is produced by the decomposition of the acid of nitre; for, after having per-formed the separation, it is capable of saturating the same quantity of alkali as before. 2. The matter of heat, which enters into the composition of both solids and fluids, and which, in a separate form, constitutes the animal heat. 3. The matter of light, which in its free state produces vision, and, when compounded, enters as an element into the composition of oil and all other inflammable parts. The eyes of animals, which shine in the night time, owe this property to the matter of light. 4. The electric matter, which enters into all bodies, and affords the phenomena of animal electricity. 5. Oxygen, which, in combination with the matter of heat, constitutes vital air; with hydrogen, forms water; with acescent bases, the acid salts of our fluids. 6. Hydrogen, which, combined with oxygen, forms water; with azot, volatile alkali; with the matter of heat, inflammable air, which is emitted from the large intestines; and with carbon, animal gas; and lastly, combined with cirbon and the sebacic acid. constitutes the oil of the adipose membrane. 7. Carbon, which, in combination with hydrogen and the sebacic acid, constitutes the oil of the adipose membrane; with hydrogen alone, animal gaz; with azot, animal gluten. 8. Sulphur, which, combined with inflammable ir, constitutes the hepatic air that exhales from muscular fibres, hair, incubated eggs, animal gluten, and, according to Lavoisier, human excrement. 9. Phosphorus, which, with oxygen, forms the phosphoric acid; and, with inflammable air, phosphoric air. The lucid sweat of some men, the phosphorescence, or light, given out by the putrefying bodies of some animals, and the phosphorus obtained from cheese and human bones, sufficiently shew that phosphorus constitutes an element of our body. 10. Soda, or the fixed mineral alkali. 11. Potash, or the fixed vegetable alkali. Each of these is found in several of the fluids of the human body. 12. An earthy element. Of the earths, no kind is so frequently detected as the calcareous, which is found in the bones and other parts. 13. A metallic element. Of so great a number of metals, iron and manganese alone are found in an organized body, whether animal or vegetable. Iron is in greater quantity in the flesh than in the bones; but in the greatest proportion in the cruor or red part of the blood. 14. An odorous principle, perceptible in all the animal fluids; but of a peculiar kind in the human urine and excrements. 15 The nervous fluid, or principle contained in the nerves, and which appears to be an element sui generis, distinct from all known fluids, and not to be collected by art.

III. The vital principle. In all solid and fluid parts of a living body, there exists an element, with properties peculiar to itself, which constitutes life; hence it is justly called vital. This principle induces a mode of union in the other elements, widely differing from that which arises from the common laws of chemical affinity. By the aid of this principle, nature produces the animal fluids, as blood, bile, semen, and the rest, which can never be produced by the art of chymistry. But if, in consequence of death, the laws of vital attraction, or affinity, cease to operate, then the element, recovering their former properties, become again obedient to the common laws of chymical affinity, and enter into new combinations, from which, new principles, or the production of putrefaction, are produced. Thus the hydrogen, combining itself with the azot, forms volatile alkali; and the carbonated hydrogen, with the azot, putrid air, into which the whole body is converted. It also appears from hence, why organized bodies alone, namely, animal and vegetable, are subject to putridity, to which inorganic or mineral substances are in no degree liable, the latter

not being compounded according to the laws of vital affinity, but only according to those of chymical affinity. For the tatiscence, or resolution of the pyrites, or ferrum sulphuratum, in the atmospheric air, is not putrefaction, but only the oxygen, furnished by the air, combining with the sulphur, and forming sulphuric acid.

Fire, as well as putridity, separates the constituent principles of animal bodies into their elements; but these, by a peculiar law, under the action of fire, again combine in a different manner, and form peculiar constituent principles, called the products of fire. Thus the hydrogen, combining with azot, is changed into volatile alkalı; but with a large proportion of carbon, it forms empyreumatic oil. From what has hitherto been said, it will also appear, that the true constituent principles of the animal body cannot be detected, either by putrefaction or the action of fire; for by these means we only discover the elements of those principles. Thus, whenever volatile alkali is tound to be generated, azot and hydrogen may be supposed to have been present in the natural state of the animal substance; and when empyreumatic oil is obtained, it may be concluded it is furnished by the hydrogen and carbon of the animal

Manaca. A Brazil shrub, whose root is

powerfully emetic and cathartic.

MANCORON. According to Oribasius, a kind of sugar, which is found in a sort of cane.

MANDIBULA. (From mando, to chew.)
The lower jaw. See Maxilla inferior.

Mandragora. (From μανθεα, a den, and αγαρα, to collect; because it grows about caves and dens of beasts; or from the German man dragen, bearing nan.) Mandrake. Atropa mandragora of Linnæus. The boiled root is employed in the form of poultice, to discuss indolent tumours.

MANDRAGORITES. (From µandgayoga, the mandrake.) Wine, in which the roots of the male mandrake are infused.

Mandrake. See Mandragora.

Manducaton. (From manduco, to chew.) The muscles which perform the action of chewing.

MANGA. (Indian.) The mango-tree.

MANGANESE. This metallic substance seems, after iron, to be the most frequently diffused metal through the earth; its ores are very common. As a peculiar metal, it was first noticed by Galia and Scheele, in the years 1774 and 1777. It is always found in the state of an oxyd, varying in the degree of oxydation. La Peyrouse affirmed that he had found manganese in a metallic state; but there was probably some mistake in his observation

MAN 469

They are distingished into grey oxyd of manganese, black oxyd of manganese, reddish white oxyd of manganese, and carbonate of manganese. All these combinations have an earthy texture; they are very ponderous; they occur both amorphous and crystallized; and generally contain a large quantity of iron. Their colour is black, blackish brown, or grey, seldom white. They soil the fingers like soot. They are sometimes crystallized in prisms, tetrahedral, rhombordal, or striated.

Properties.—Manganese is of a whitish grey colour. Its fracture is granulated, irregular, and uneven. It is of a metallic brilliancy, which it, however, soon loses in the air. Its specific gravity is about 6.850. It is very hard, and extremely brittle. It is one of the most refractory metals, and most difficult to fuse, requiring at least 163° of Wedgwood's py-Its oxydability is so rapid, that rometer. exposure to the air is sufficient to render it red, brown, black, and friable, in a very short time; it can, therefore, only be kept under water, oil, or ardent spirit. It is the most combustible of all the metals. It decomposes water, by heat very rapidly, as well as the greater part of the metallic oxyds. It decomposes sulphuric acid. 1t is soluble in nitric acid. It is fusible with earths, and colours them brown, violet, or red, according to its state of oxydation. It discolours glasses tinged by iron. It does not appear to unite with sulphur. It combines with phosphorus. It unites with gold, silver, and copper, and renders them brittle. It unites to arsenic in close vessels, but does not enter into union with mercu-It forms three differently coloured ry. oxyds, by combining with different portions of oxygen.

Method of obtaining Manganese.—This metal is obtained by mixing the black oxyd, finely powdered, with pitch; making it into a ball, and putting this into a crucible, with powdered charcoal, one-tenth of an inch thick at the sides, and one-fourth of an inch deep at the bottom. The empty space is then to be filled with powdered charcoal; a cover is to be luted on; and the crucible exposed, for an hour, to the strongest heat that can be raised. digest the black oxyd of manganese repeatedly, with the addition of one-sixteenth of sugar, in nitric acid; dilute the mixture with three times its bulk of water; filter it, and decompose it by the addition of potash; collect the precipitate, form it into a paste with oil, and put it into a crucible. well lined with charcoal. Expose the crucible for at least two hours to the strongest heat of a forge.

Manganese may also be obtained in the following manner:

Prepare a saturated solution of sulphate

of manganese, bring it to a boiling heat, and add to it, gradually, a solution of tarrite of potash, until no further precipitate ensues; then filter the solution, and wash the precipitate in water, and when dry make it into a paste with oil, and proceed as before.

In this process, the sulphuric acid unites to the potasn, and forms sulphate of potash, and the tartareous acid joins to the manganese, and forms a tartrite of manganese, which is decomposable by heat.

Mangel Wursel. The root of scarcity. A plant of great importance, as a substitute for bread in periods of famine. It has not, however, succeeded so well in this country as in Germany. It is properly a species of beet.

Mangifera Indica. The systematic name of the mango-tree. See Mango.

Mango. The fruit of the Mangifera

Mango. The fruit of the Mangifera Indica of Linnaus, which is cultivated all over Asia. When ripe, they are juicy, of a good flavour, and so fragrant as to perfume the air to a considerable distance. They are eaten either raw or preserved with sugar. Their taste is so luscious, that they soon pall the appetite. The unripe fruits are pickled in the milk of the cocoa-nut that has stood until sour, with salt, capsicum, and garlic. From the expressed juice is prepared a wine; and the remainder of the kernel can be reduced to an excellent flour for the making of bread.

MANGOSTANA. See Mangosteen.

MANGOSTEEN. A fruit about the size of an orange, which grows in great abundance on the tree called Garcinia Mangostana by Linneaus, in Java and the Molucca islands. According to the concurring testimonies of all travellers, it is the most exquisitely flavoured, and the most salubrious of all fruits, it being such a delicious mixture of the tart and sweet. The flesh is juicy, white, almost transparent, and of a more delicate and agreeable flavour than the richest grape. It is eaten in almost every disorder, and the dried bark is used medicinally in dysenteries and tenesmus, and a strong decoction of it is much esteemed as a gargle in ulcerated sore throats.

Mangosteen bark. See Mangosteen.

MANIA. (From μ21/10/221, to rage.) Raving or furious madness. A genus of disease in the class neuroses, and order vesamic of Cullen. The definition of mania is delirium, unaccompanied with fever; but this does not seem altogether correct, as a delirium may prevail without any frequency of pulse, or fever; as happens sometimes with women in the hysteric disease. In mania, the mind is not perfectly master of all its functions; it receives impressions from the senses, which are very different from those produced in health;

the judgment and memory are both lost, and the irritability of the body is much diminished, being incapable, it is supposed, of resisting the usual morbid effects of cold, hunger, and watching, and being likewise less susceptible of other diseases than before.

Mania may be said to be a false perception of things, marked by an incoherence, or raving, and in a resistance of the passions to the command of the will, accompanied, for the most part, with a violence of action, and furious resentment at restraint.

There are two species of madness, viz.

the metancholic and furious.

Machess is occasioned by affections of the mind, such as anxiety, grief, love, religion, terror, or enthusiasm; the frequent and uncurbed indulgence in any passion, or emotion, and by abstruse study. It short, it may be produced by any thing that affects the mind so forcibly as to take off its attention from all other affairs. Violent exercise, frequent intoxication, a sedentary life, the suppression of periodical and ocsasional discharges and secretions, excessive evacuations, and paralytic seizures, are likewise enumerated as remote Certain diseases of the febrile kind have been found to occasion madness, where their action has been very violent. In some cases it proceeds from an hereditary predisposition. Two constitutions are particularly the victims of madness; the sanguine and melancholic; by the difference of which its appearance is somewhat modified. Each species of mania is accompanied with particular symptoms. Those which attend on the melancholic are, sadness, dejection of spirits, and its at-Those which accompany an attack of furious madness arc, severe pains in the head, redness of the face, noise in the ears, wildness of the countenance, rolling and glistening of the eyes, grinding of the teeth, loud roaring, violent exertion of strength, absurd, incoherent discourse, nuaccountable malice to certain persons, particularly to the nearest relatives and friends, a dislike to such places and scenes as formerly afforded particular pleasure, a diminution of the irritability of the body, with respect to the morbid effects of cold, hunger and watching, together with a full, quick pulse.

Mania comes on at different periods of life; but, in the greater number of cases, it makes its attack between thirty and forty years of age. Females appear to be more subject to mania than males.

Dissections of maniacal cases, Dr. Thomas observes, most generally shew an effusion of water into the cavities of the brain; but, in some cases, we are able to discover evident marks of previous in-

flammation, such as thickening and opacity of the tunica arachnoides and pia mater. In a few instances, a preternatural hardness of the substance of the brain.

From Dr. Greding's observations, it appears that the skulls of the greater number of such persons are commonly very thick. Some he found of a most extraordinary degree of thickness; but it appears that the greater number of insune people die of atrophy and hydrothorax.

MANIHOT. The latrophe manihot.

MANIPULUS. (Quad manum, implest b

Manipulus. (Quod manum, implest, because it fills the hand.) A handful.

Manjapumeram. A common tree in the the West Indies, the flowers of which are distilled, and the water used against in-

flammations of the eyes.

MANNA. (From mano, a gift, Syr. it being the rood given by God to the children of Israel in the wilderness; or from malma, what is it? an exclamation occasioned by their wonder at its appearance.) Manna calabrina. Ros calabrinus. Acromeli. Alusar. Drysomeli. That species which is of of a rosy colour, is called nuba. Mel aerium. from the supposition that it descended from heaven. The condensed juice of the flowering ash, or, Fraxinus ornus: -follis ovato-oblongis serratis petiolatis, floribus corrollatis. Hort. Kew, which is a native of the southern parts of Europe, particularly Sicily and Calabria. Many other trees and shrubs have likewise been observed to emit a sweet juice, which concretes upon exposure to the air, and may be considered of the manna kind, especially the Fraxinus rotundifolia and excelsior. In Sicily, these three species of fraxinus are regularly cultivated for the purpose of procuring manna, and with this view are planted on the declivity of a hill with an eastern aspect. After ten years growth, the trees first begin to yield the manna, but they require to be much older, before they afford it in any considerable quantity. Although the manna exudes spontaneously upon the trees, yet, in order to obtain it more copiously, incisions are made through the bark, by means of a sharp crooked instrument; and the season thought to be most favourable for instituting this process is a little before the dog-days commence, when the weather is dry and serene. Manna is generally distinguished into different kinds, viz. the manna in tear, the canulated and flaky manna, and the common brown or fat manna. All these varieties seem rather to depend upon their respective purity, and the circumstance in which they are obtained from the plant, than upon any essential difference of the drug. The best manna is in oblong pieces, or flakes, moderately dry, friable, very light, of a whitish or pale vellow colour, and in some degree transparent: the inferior kinds are

moist, unctons, and brown. Manna is well known as a gentle purgative, so mild in its operation, that it may be given with safety to children and pregnant women, to the delicacy of whose frames and situation it is particularly adapted. It is esteemed a good and pleasant auxiliary to the purgative neutral salts. It sheathes aerimony, and is useful in coughs, disorders of the breast, and such as are attended with fever and inflammation, as in pleuritis, &c. Its is particularly efficacious in bilious complaints, and helps the discharge of mineral waters, when they are not of themselves sufficiently active. It is apt to create flatulencies and gripes; both which are prevented by a small addition of some warm carmitive. It purges in doses of from \$\overline{3}\) to \$\overline{3}\overline{j}\); but its purgative quality is much increased, and its flatulent effects prevented, by a small addition of cassia. The dose for children is from one scruple to three. It is best dissolved in whey.

MANNA BRIGANTIACA. A species of manna brought from Brianconois in Dau-

MANNA CALABRINA. Calabrian manna. Flaky mannna, or MANNA CANULATA. manna concreted on straw, or chips.

MANNA SECUNDA. An inferior or second sort of manna.

MANNA THURIS. A coarse powder of olibanum.

MANNIFERA ARBOR. (From manna, and fero, to bear.) The fraxious ornus.

MANSORIUS. (From mando, to chew.) The masseter muscle.

MANTILE. The name of a bandage. Manus ner. A name of a resolvent plaster, which is described by Lemery. Also for opium.

Mapple. See Saccharum canedense. A species of myrtle, grow-MARANDA. ing in the island of Zeylon, a decoction of the leaves of which are said to be excellent

against the venereal disease.

MARANTA. 1. The name of a genus of plants in the Linnman system. Class, Order, Monogynia. Monandria.

2. The name of the Indian arrow-root. There are three species of Maranta, the Arun linacea, Galanga, and Comesa, all of their herbaceous, perennial exotics of the Indies, kept here in hot-houses for curiosity; they have thick, knotty, creeping roots, crowned with long, broad, arandinaccous leaves, ending in points, and upright stalks half a yard high, terminated by bunches of monopetalous, ringent, fiveparted flowers. They are propagated by parting the roots in spring, and planting them in pots of light rich earth, and then plunging them in the bark-bed. The root of the Maranta Galanga, commonly called arrow-root, is used by the Indians to extract the virus communicated by their

poisoned arrows, from whence it has obtained its name. It is cultivated in gardens and provision-grounds in the West Indies; and the starch is obtained from it by the following process: The roots, when a year old, are dug up, well washed in water, and then beaten in a large deep "noden mortar to a pulp; this is thrown into a large tub of clean water: the whole is then well stirred, and the fibrous part wrung out by the hands, and thrown away. The nilky liquor being passed through a hair sieve, or coarse cloth, is suffered to settle, and the clear water drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water, and drained: lastly, the mass is dried on sheets in the sun, and is pure starch.

Arrow-root contains, in small bulk, a greater proportion of nourishment than any other yet known. The powder, boiled in water, forms a very pleasant transparent jelly, very superior to that of sago or tapioca; and is much recommended as a nutritious diet for children and invalids. The jelly is made in the following manner: to a desert spoonful of powder, add as much cold water as will make it into a paste; then pour on half a pint of boiling water: stir it briskly, and boil it a few minutes, when it will become a clear smooth jelly; a little sugar and sherry wine may be added for debilitated patients; but for infants, a drop or two of essence of caraway-seeds. or cinnamon, is preferable, wine being very liable to become acescent in the stomachs of infants, and thus disagree with the bowels. Fresh milk, either alone or diluted with water, may be substituted for the water. For very debilitated frames, and especially for rieketty children, this jelly, blended with an animal jelly, as that of the stag's horn (rasuræ cornu cervi,) affords a more nutritious diet than arrowroot alone, which may be done in the following manner: Boil half an ounce of stag's horn shavings, in a pint of water, for fifteen minutes; then strain, and add two desert spoonfuls of arrow-root powder, previously well mixed with a tea-cupful of water; stir them briskly together, and boil them for a few minutes. If the child should be much troubled with flatulency, two or three drops of essence of carawayseeds, or a little grated nutmeg, may be added; but for adults, port wine, or brandy, will answer best.

MARASMUS. (From mogano, to grow lean.) Atrophia. Emaciation. A wasting away of the flesh, without fever or apparent disease. See Atrophy.

MERATRITES. (From μαςαθεον, fennel.) A vinous infusion of fennel; or wine impregnated with fennel.

MARATHROPHYLLUM. (From magabou, fennel, and puncer, a leaf; so named because its leaves resemble those of the common fennel.) See Peucedanum officinale.

MARATHRUM. (From μαςαινώ, to wither; so called because its stalk and flowers wither in the autumn.) See Faniculum.

MARATHRUM SYLVESTRE. See Peucedanum.

MARBLE. Powdered marble, which is a carbonate of lime, is used in pneumatic medicine, to give out carbonic acid gaz.

Marcasite. See Bismuth.

MARCASSITA. (From marcasite, Germ.) See Bismuth.

MARCHANTIA POLYMORPHA. The systematic name of the liver-wort. See Hepati-

MARCORES. (From marceo, to become lean.) Universal emaciation. The first order in the class cachexia of Cullen's nosology.

Marestail. See Equisetum

MARGARITA. (From margalith, Rab.) 1. The pearl; Perla. Unio. A small calcar ous concretion, of a bright transparent whiteness, found on the inside of the shell Concha margaritifera of Linnæus, or mother-of-pearl fish. Pearls were formerly exhibited as antacids.

2. A tumour upon the eye resembling a

pearl.

MARIGOLD, MARSH. Caltha palustris of Linnæus. The flower buds of this very common plant may be pickled as a good substitute for capers.

Marine acid. See Muriatic acid. Marine salt. See Murias soda.

MARIPENDAM. A plant in the island of St. Domingo: its tops are distilled, and thus a water is obtained, which is held in great esteem against pains in the stomach.

Marisca. An excrescence about the anus, or the piles in a state of tumefaction;

the Hamorrhois tumens of Cullen.

Marisicum. The merculiaris f uticos?. Marjoram, sweet. See Majorana. Marjoram, wild. See Origanum.

MARJORANA. See Origanum.

The pulp of quinces, or MARMALADE. any other fruit, boiled into a consistence with honey.

MARMARYGE.. (From pagpage, to shine.) An appearance of sparks, or coruscations,

flushing before the eyes,

MARMOLARIA. (From marmor, marble; so named because it is spotted like marble.) Bear's-breech. See Acanthus mol-

(From marmor.) MARMORATA AURIUM. Ear-wax.

MARMORIGE. A variety of the Pseudoblepsis Imaginaria, in which sparks and flashes of fire are supposed to present themselves.

MARMOREUS TARTARUS. The hardest species of human calculus.

A purgative extract MAROCOSTINUM. made of the marum and costus; originally made by Mindereus.

The fat sub-MARROW. Medulla. stance secreted by the small arteries of its proper membrane, and contained in the medullary cavities of the long cylindrical bones. See Bones.

Marrow, spinal. See Medulla spinalis.

MARRUBIASTRUM. Ballota, or stinking horehound.

MARRUBIUM. ((From marrob, a bitter jnice, Heb.) Mauro-marson. 1. The name of a genus of plants in the Linnaan system. Class, Didynamia. Order, Gymnospermia.

2. The pharmacopoial name of the common white horehound. Marrubium album. Marrubium vulgare of Linnaus:dentibus calcynis setaceis uncinatis. The leaves of this indigenous plant have a moderately strong smell of the aromatic kind, but not agreeable; which, by drying, is improved; and in keeping for some months is in great part dissipated; their taste is very bitter, penetrating, diffusive, and durable in the mouth. That horehound possesses some share of medicinal power, may be inferred from its sensible qualities, but its virtues do not appear to be clearly ascertained. It is a favourite remedy with the common people in coughs and asthmas. The usual dose is from half an ounce to an ounce, in infusion, two or three times a day. The dose of the extract is from gr. x to 3ss.

MARRUBIUM ALBUM. See Marrubium. MARRUBIUM AQUATICUM. Water hore-

hound; opening, corroborant.

MARRUBIUM HISPANICUM. Mad-wort. or Spanish horehound.

MARRUBIUM NIGRUM FŒTIDUM. black stinking horehound, or ballota.

MARRUBIUM VERTICILLATUM. bium hispanicum. The base horehound. Galen's madwort.

The systematic MARRUBIUM VULGARE. name of the common horehound. See Marrubium.

MARS. The alchemists gave this name to iron.

MARS ALKALIZATUS SOLUBILIS. Iron and fixed alkali.

MARS SACCHARATUS. Iron mixed with

starch and melted sugar. MARS SOLUBILIS. Ferrum tartarizatum. Iron filings, and MARS SULPHURATUS.

sulphur dephiagrated. Marseilles hart-wort. See Seseli massi-

Marsh-mallow. See Althea.

Marsh trefoil. See Trefolium paludosum. MARSUPIALIS. (Marsupialis, sc musculus; from marsupium, a purse; so named from its resemblance.) See Obturator internus.

MARTAGON LILY. Lilium martagon of Linnæus, who informs us the root makes part of the daily food of the Siberians.

MARTIAL. Sometimes used to express preparations of iron, or such as are impregnated therewith; as the Martial Regulus of antimony, &c.

MARTIATUM UNGUENTUM. Soldiers' ointment. Ointment of laurel, rue, mar-

joram, &c.

MARTIS ESSENTIA. A solution of lead in acid. MARTIS LIMATURA PRÆPARATA. Puri-

fied filings of iron. MARUM CRETICUM.

See Marum Syri-

MARUM SYRIACUM. (From mar, bitter, Heb.) Marum creticum. Majorana syriaca. Marum verum. Marum Coortusi. Chamædrys incana maritima. Marum germander, or Syrian herb mastich. This shrub is the Teucrium marum of Linnaus: -foliis integerrimis ovatis acutis petiolatis, subtus tomentoris, floribus sacemosis secundis. It grows plentifully in Greece, Ægypt, Crete, and Syria. The leaves and younger branches, when recent, on being rubbed betwixt the fingers, emit a volatile aromatic smell, which readily excites sneezing; to the taste they are bitterish, accompanied with a sensation of heat and acrimony. Judging from these sensible qualities of the plant, it may be supposed to possess very active powers. It is recommended as a stimulant, aromatic, and deobstruent; and Linnæus, Rosenstein, and Bergins, speak highly of its utility. Dose, ten grains to half a drachm of the powdered leaves, given in wine. At present, however, marum is chiefly used as an errhine.

MARUM VERUM. See Marum syriacum. MARUM VULGARE Common herb mastich. Sampsuchus. Clinopodium mastichina gallorum. Thumbra hispanica. Jaca indica. Thymus mastichina of Linnæus. A low shrubby plant, a native of Spain, which is employed as an errhine. It has a strong agreeable smell, like mastich. Its virtues are similar to those of marum

syriacum, but less powerful.

Maryisum. Malmsey wine.

Maschale, (Μασχαλη.) The arm-pit.

Maschalister. (From μασχαλιςης.) The second vertebræ of the back.

MASLACH. A medicine of the opiate kind,

in use amongst the Turks.

MASPETAM. Maspetum. The leaves of

the asafætida plant.

MASSA. (From μασσω, to blend together.) A mass. A term generally applied to the compound out of which pills are to be formed.

MASSA CARNEA JACOBI SYLVII. Flexor longus digitorum pedis.

Massalis. A name for mercury.

MASSETER. (From μασσαομαι, to chew; because it assists in chewing.) Zigomato-maxillaire of Dumas. A muscle of the lower jaw, situate on the side of the face. It is a short thick muscle, which arises, by fleshy and tendinous fibres, from the lower edge of the malar process of the maxillary bone, the lower horizontal edge of the os malz, and the lower edge of the zygomatic process of the temporal bone, as far backwards as the eminence belonging to the articulation of the lower jaw. From some little interruption in the fibres of this muscle, at their origin, some writers describe it as arising by two, and others by three, distinct portions, or heads. The two layers of fibres of which it seems to be composed cross each other as they descend, the external layer extending backwards, and the internal one slanting forwards. It is inserted into the basis of the coronoid process, and into all that part of the lower jaw which supports the coronoid and condyloid processes. Its use is to raise the lower jaw, and, by means of the above-mentioned decussation, to move it a little forwards and backwards in the act of chewing.

Massicot. Calcined white lead.

MASSOY CORTEX. See Cortex massoy. Masterwort. See Imperatoria.

MASTICATION. (Masticatio; from mastico, to chew.) Chewing. A natural function. The mixing together and dividing of the particles of the food in the mouth, by the action of the jaws, tongue, lips, and cheeks. By means of this function, the food is lacerated and mixed with the saliva and the mucus of the mouth and fauces, and thus made into a bole of such a consistence as to be formed into a convenient size to be swallowed. See Deginti-

MASTICATORIES. (Masticatoria, sc. medicamenta; from Mastico, to chew.) Such medicines as are intended for chew-

MASTICHE. (From μασσω, to ex-Mastich. The tree press.) Mastix. which affords this resin is the Pistachia lentiscus; foliis abrupte pinnatis, foliis lan-ceolatis of Linnaus. A native of the south of Europe. In the island of Chio the officinal mastich is obtained most abundantly, and, according to Tournefort, by making transverse incisions in the bark of the tree, from whence the mastich exudes in drops, which are suffered to run down to the ground, when, after sufficient time is allowed for their concretion, they are col-lected for use. Mastich is brought to us in small, yellowish, transparent, brittle tears, or grains; it has a light agreeable smell, especially when rubbed, or heated; on bein chewed, it first crumbles, soon after sticks together, and becomes soft

and white, like wax, without impressing any considerable taste. It is considered to be a mild corroborant and adstringent; and, as possessing a balsamic power, it has been recommended in hæmoptysis, proceeding from ulceration, lencorrhæa, debility of the stomach, and in diarrheas and internal ulcerations. Chewing this drug has likewise been said to have been of use in pains of the teeth and gums, and in some catarrhal complaints: it is, however, in the present day, seldom used either externally or internally. The wood abounds with the resinous principle, and a tincture may be obtained from it, which is esteemed in some countries in the cure of hæmorrhages, dysenteries, and gout.

Mastich tree. See Mastiche.

Mastich herb, common. See Marum vul-

Mastich herb, Syrian. See Marum Syri-

Mastich wood. See Mastiche.

(From masixn, mas-MASTICHELÆUM. MASTICHELÆUM. (From μαςιχη, tich, and ελαιον, oil.) Oil of mastich.

MASTICHIA. (From μασιχη, mastich; so called because it smells like mastich.) Nux virginiana, or mastich of ligon.

MASTICHINA. (Dim. of mastiche.) Mastichina gallorum marum, or mastich thyme. See Marum vulgare.

Masticot. See Massicot. MASTIX. See Mastiche.

MASTODYNIA. (From M2505. breast, and odown, pain.) Phlegmon of the breast of women. This disease may take place at any period of life, but it most commonly affects those who give suck. It is characterized by tumefaction, tension, heat, redness, and pain; and comes sometimes in both breasts, but most commonly in one. Pyrexia generally attends the disease. It is sometimes very quickly formed, and in general without any thing preceding to shew it; but now and then a slight shivering is the forerunner. This disease terminates either in resolution, in suppuration, or schirrus. If the disease is left to itself, it generally terminates in suppuration.

The causes which give rise to this disease are those which give rise to most of the phlegmasiz, as cold, violent blows, &c. women who are lying in, or giving suck, it mostly arises either from a suppression of the lochia or a retention of milk. Mastodynia is often of long continuance; it is a very prinful disease, but it is seldom fatal, unless when absolutely neglected, when it may run into scirrhus, and finally cancer. The termination of the disease by gangrene is never to be apprehended; at least few, if any, have seen the disease terminate in this

way.

MASTOID. (Mastoideus; from masos, a breast, and edos, resemblance.) 1. Those processes of bones are so termed that are shaped like the nipple of the breast.

2. The name of a muscle which is insert-

ed into the mastoid process.

MASTOIDÆUM FORAMEN. A hole in the temporal bone of the skull.

MASTOIDEUS LATERALIS. A name for the

complexus.

MASTOIDEUS. (From masoidus, the mas-See Sterno-cleido-mastoitoid process.)

MATALISTA RADIX. A root said to be imported from America, where it is given as a purgative, its action being rather milder than that of jalap.

MATER. (Marne, a mother.) Two membranes of the brain had this epithet given them by the Arabians, who thought they gave origin to all other membranes of the body. See Dura mater and Pia mater. Also a name of the herb mugwort, because of its virtue in disorders of the womb.

MATER DURA. See Dura mater.

MATER HERBARUM. Artemisia, or common mugwort.

MATER METALLORUM. Quicksilver. MATER PERLARUM. Mother of pearl. The concha margaritifera.

MATER PIA. See Pia mater.

MATERIA PERLATA. If, instead of crystallizing the salts contained in the liquor separated from diaphoretic antimony, an acid be poured into it, a white precipitate is formed, which is nothing else but a very refractory calx of antimony.

MATERIATURA. Castellus explains morbi materiaturæ to be diseases of intempe-

MATERIA MEDICA. By this term is understood a general class of substances, both natural and artificial, which are used in the cure of diseases.

Cartheuser, Newman, Lewis, Gleditsch, Linnæus, Vogel, Alston, and other writers on the Materia Medica, have been at much labour to contrive arrangements of these articles. Some have arranged them according to their natural resemblances; others according to their real or supposed virtues; others according to their active constituent

principles.

These arrangements may have their peculiar advantages. The first may be preferred by the natural historian, the second by the physiologist, and the last by the The pharmacopæias published by the Colleges of Physicians of London, Dublin, and Edinburgh, have the articles of the Materia Medica arranged in alphabetical order; this plan is also adopted by almost all the continental pharmacopaias.

```
Dr. Cullen has arranged the Materia Medica as follows :--
         NUTRIMENTS, which are
                        Food,
                        Drinks.
                        Condiments;
          MEDICINES which act on the
              Solids,
                            Simple, as
                                   Astringents,
                                   Tonics,
                                   Emmollients,
                                   Corrosives;
                            Living, as
                                   Stimulants,
                                   Sedatives,
                                          Narcotics,
                                          Refrigerants,
                                   Antispasmodics.
              Fluids,
                     Producing a change by
                       fluidity,
                                Attenuants.
                                 Inspissants.
                       Mixture,
                              Correctors of Acrimony,
                                     Demulcents,
                                     Antacids.
                                     Antalkalines,
                                     Antiseptics.
                     Evacuants, viz.
                                     Errhines,
                                     Sialogogues,
                                     Expectorants
                                     Emetics,
                                     Cathartics,
                                     Diuretics,
                                     Diaphoretics,
                                     Menagogues.
    The following is the list of articles which come under the preceding classes :-
  I. NUTRIMENTS.
                               Olives
                                                           2. Tonics.
z. FRUITS.
                                   II. MEDICINES.
                                                             Gentian
  a. Fresh, sweet, acidulous, 1. ASTRINGENTS.
                                                             Lesser centaury
    35
                               Red rose
                                                             Quassia
  Prunes
                               Cinquefoil
                                                             Simarquba
  Oranges
                               Tormentil
                                                             Marsh trefoil
  Lemons
                               Madder
                                                             Fumatory
  Raspberries
                                                             Camomile
                               Sorrel
  Red and black currants
                                                             Tansy
                               Water-dook
  Mulberries
                               Bisturt
                                                             Wormwood
  Grapes
                                                             Southernwood
                               Fern
  b. Dried, sweet, acidulous,
                                                             Sea-wormwood
                               Granate
    ns
                               Oak-bark
                                                             Water-germander
  Raisins
                               Galls
                                                             Virginian snakeroot
  Currants
                               Logwood
                                                             Leopard's bane
  Figs.
                               Quince
                                                             Peruvian bark.
3. OLERACIOUS HERBS.
                               Mulberry
                                                          3. EMOLLIENTS.
  Water-cresses
                                                             Columniferous,
                               Sloe
  Dandelion
                               Gum-arabic
                                                             Marsh mallow
  Parsley
                               Catechu
                                                             Mallow.
  Artichoke.
                                                             Farinaceous,
                               Dragon's blood
y. Roots,
                               Alkanet
                                                             Quince-seeds
  Carrot
                               Balustine flower
                                                             Fænu greek-seed
  Garlick
                               St. John's wort
                                                             Linseed.
                               Millefoil
  Satyrion.
                                                             Various emollients,
J. SEEDS and NUTS,
                               Plantain
                                                             Pellitory

D. Mechanical remedies. Anthelmintics. Demulcents Dituents Emollients.

Under the head of Nancorics are in-

cluded--

Alkohol. Ether. Camphor, Papaver somniferum. Hyoscyamus niger. Auropa Confum belladona. Aconitum napellus. maculatum. Digitalis purpurea. Nicotiana tabacum. Lactuca virosa. Datura Rhododendrum chrysanstramonium. thum. Rhus toxicodendron. Arnica mon-Strychnos nux vomica. Prunus lauro cerassus.

Under the second class, Antispasmonics, are included-Moschus. Castoreum, Ole-Petrole. um animale empyreumaticum. um Ammonia. Ferula asafoetida. gapenum. Bubon galbanum. Valeriana officinalis. Crocus sativus. Melaleuca leucadendron.

. Narcotics used as Antispasmodics-Ether. Camphor. Opium.

Tonics used as Antispasmodics-Cuprum. Zincum. Hydrargyrus. Cinchona.

The head of Toxics embrace-1. From the mineral kingdom,

Serpentary Sage

Water germander Guaiacum

Sassafras Seneka Vegetable acids Essential oil

Wine Diluents.

23. EMMENAGOGUES. Aioe

Fætid gums Fœtid plants Saffron.

Calx. Arsenicum. Barytes. Acidum. Oxy-murias potassæ. Nitricum.

2. From the vegetable kingdom,

Cinchona officinalis. Cinchona caribæa. Cincliona floribunda. Angustura. Aristolochia serpentaria. Dortenia contrayerva. Croton eleutherla. Calomba. Quassia excelsa. Quassia Simarouba. tenia febrifuga. Swietenia mahagoni. Gentiana leutea. Anthemis nobilis. Artemesia absıntlıium. Chironia centaurium. Marrubium vulgare. Menyanthes trifoliata. Centaurea benedicta. Citrus aurantium. Citrus medica. Laurus cinnamomum. Laurus cassia. Canella alba. Acorus calamus. Amomum zinziber. Kæmferia rotunda. Santalum album. Pterocarpus santalinus. Myristica moschata. Caryophyllus aromaticus. Capsicum annuum. Piper nigrum. Piper longum. Piper cubeba. Myrtus pimenta. Amomum repens. Carum carui. Coriandrum sativum. Pimpenella anisum. Anethum fæniculum. Anethum graveolens. Cuminum cyminum. Angelica archangelica. Mentha piperita. Mentha viridis. Mentha pulegium. Hyssopus officinalis.

The class of ASTRINGENTS comprehends

the following :-

1. From the vegetable kingdom. Quercus rubor. Quercus cerris. Tormentilla erecta. Polygonum bistorta. Anchusa tinctoria. Hæmatoxylon campechianum. Rosa gallica. Arbutus uva Mimosa catechu. Kino. l'teroursi. carpus draco. Ficus indica. Pistachia lentiscus.

From the mineral kingdom.

Acidum sulphuricum. Argilla. Super sulplias argillæ et potassæ. Calx. nas calcis. Plumbum. Zincum. Ferrum. Cuprum.

The articles which come under the head of Emmerics are,

I. From the vegetable kingdom.

Callicocca ipecacuanha. Scilla maritima. Anthenus nobilis. Sinapis alba. Europœum. Nicotiana tabacum.

2. From the mineral kingdom.

Antimonium. Sulphas zinci. Sulphas cupri. Subacetas cupri. Ammenia, Hy-Hydrargyrus, Ferrum, Zmcum, Cuprum, dro-sulphuretum ammonia.

CATHATRTICS include

Laxatives. Manna. Cassia fistula.

Tamarindus Indica. Ricinus communis.

Sulphur. Magnesia.

Purgatives. Cassia senna. Rheum paltum. Convolvolus jalapa. Helleborus niger. Brionia alba. Cucumis colocynthis Momordica elaterium. Rhainmus catharticus. Aloe perfoliata. Convolvolus scammonia. Gambojia gutta. Submurias hydrargyri. Sulphas magnesia, Sulphas sodæ. Sulphas potasæ. Supertartris potassæ. Tartris potassæ et sodæ. Murias sodæ. Terebinthina veneta. Nicotiana tabacum,

The medicines arranged under EMMENA-

GOGUES are,

 From the class of Antispasmodics, Castoreum. Ferula asafætida. Bubon galbanum.

2. From the class of Tonics,

Ferrum. Hydrargyrus. Cinchona officinalis.

3. From the class of Cathartics,

Aloe. Helleborus niger. Sinapis alba. Rosmarinus officinalis. Rubia tinctorum. Ruta graveolens. Juniperus sabinæ.

The class of DIURETICS includes,

1. Saline diuretics.

Supertartris potassæ. Nitras potassæ. Murias ammoniæ. Acetis potassæ. Potasssa.

a. From the vegetable kingdom,

Scilla maritima. Digitalis purpurea. Nicotiana tabaccum. Solanum dulcamara. Latuca virosa. Colchicum autumnale. Gratiola officinalis. Spartium scoparium. Juniperus conumnis. Copaifera officinalis. Pinus balsamea. Pinus larix.

b. From the animal kingdom.

Meloe vesicatorius.

Under the class DIAPHORETICS are,

Ammonia. Murias ammoniæ. Acetis ammoniæ. Citras ammoniæ. Submurias lydrargyri. Antimonium. Opium. Camphor. Guaiacum officinale. Dapline mazereum. Smilax sarsaparilla. Laurus sassafras. Cochlearia armoracia. Salvia officinalis.

The class Expectorants comprehends, Antimonium. Ipecacuanha Nicotiana tabaccum. Digitalis purpurea. Scilla maritima. Allium sativum. Polygala senega. Ammoniacum. Myrrha. Styrax benzoin. Styrax officinalis. Toluferia balsamum. Myroxylen peruiferum. Amyris gilcadensis.

The articles of the class SIALAGOGUES are, Hydrargyrus, Anthemis pyrethrum. Arum maculatum. Amomum zinziber. Dapline mezcreum. Nicotiana tabaccum.

The class of Errhines are, Iris florentina. Æsculus hippocastanum Origanum majorana. Lavendula spica. Asarum Europæum. Veratrum album. Nicotiana tabaccum. Euphorbia officinalis.

In the class Epispastics and Ruberacients are, Meloe vesicatorius. Ammonia. Pix Burgundica. Sinapis alba. Al-

lium sativum.

Refrigerants are constituted by the following articles. Citrus aurantium. Citrus medica. Tamarindus Indica. Acidum aceto-um. Supertartris potassæ. Nitras potassæ. Boras sodæ.

The list of articles that come under the class Antacips are, Potassa. Soda. Ammonia. Calx. Carbonas calcis. Mag-

nesia.

In the class Lithontriptics are, Potassa. Carbonas potassæ. Soda. Carbonas

sodæ. Sapo albus. Calx.

In the class Escharotics are, Acida mineralia, Potassa. Nitras argenti. Murias antimonii. Sulphas cupri. Acetis cupri. Murias hydrargyri. Subnitras hydrargyri. Oxydum arsenici album. Juniperus sabina.

In the class Anthelmintics are, Dolichos pruriens. Ferri limatura. Stannum pulveratum. Olea Europæa. Artemesia santonica. Spigelia marilandica. Polypodium filix mas. Tancaetum vulgare. Geoffreca inermis. Gambojia gutta. Submurias lydrargyri.

Demulcents are, Mimosa nilotica. Astragulus tragacantha. Linum usitatissimum. Althæna officinalis. Malva sylvestris. Gylcyrrhiza glabra. Cycas circinalis. Orchis mascula. Maranta arundinacea. Triticum hybernum. Icthyocolla. Olea Europæa. Amygdalus communis.

Sevum ceti. Cera.

Water is the principal article of the class DILUENTS; and as for the last class, ENOLLIENTS, heat conjoined with moisture is the principal, though all unctuous applications may be included.

The New London Pharmacopæia presents us with the following list for the Materia

Medica:—

affords a mineral water of the acidulous

MATLOCK. A village in Derbyshire went. Several of these springs possess a temperature of 66°. Matlock water scarce. class; its abundant springs same from a ly differs from common good spring water, lime-stone rock, near the banks of the Derin sensible properties. It is extremely transparent, and exhales no vapour, excepting in cold weather. It holds little or no excess of aerial particles; it curdles soap, when first taken up, but it loses this effect upon long keeping, perhaps from the deposition of its calcarcous salts: it appears to differ very little from good spring water, when tasted; and its effects seem referable to its temperature. It is from this latter circumstance that it forms a proper tepid bath for the nervous and irritable, and those of a debilitated constitution; hence it is usually recommended after the use of Bath and Buxton waters, and as preparatory to sea-bathing.

MATRICALIA. (From matrix, the womb.)
Medicines appropriated to disorders of the

MATRICARIA. (From matrix, the womb; so called from its uses in disorders of the womb. Parthenium. Febrifuga. Common fever-few, or febrifuge, and often, but very improperly, feather-few. Mother's wort. The leaves and flowers of this plant Matricaria parthenium :- foliis compositis, planis; foliolis ovatis, incisis; pedunculis ramosis, have a strong, not agreeable, smell, and a moderately bitter taste, both which they communicate, by warm infusion, to water and rectified spirit. The watery infusions, inspissated, leave an extract of considerable bitterness, and which discovers also a saline matter, both to the taste, and in a more sensible manner by throwing up to the surface small crystalline efflorescences in keeping. The peculiar flavour of the matricaria exhales, in the evaporation, and impregnates the distilled water, on which also a quantity of essential oil is found floating. The quantity of spirituous extract, according to Cartheuser's experiments, is only about one-sixth the weight of the dry leaves, whereas the watery extract amounts to near one-half. This plant is evidently the Parthenium of Dioscorides, since whose time it has been very generally employed for medical purposes. In natural affinity, it ranks with camomile and tansy, and its sensible qualities shew it to be nearly allied to them in its medicinal character. Bergius states its virtues to be tonic, stomachic, resolvent, and emmenagogue. It has been given successfully as a vermifuge, and for the cure of intermittents; but its use is most celebrated in female disorders, especially in hysteria; and hence it is supposed to have derived the name matricaria. Its smell, taste, and analysis, prove it to be a medicine of considerable activity; we may therefore say, with Murray-Rarius hodie præscribitur, quam

MATRICARIA CAMMONILLA. The systematic name of the common fever-few. See Chamæmælum vulgare.

MATRICARIA PARTHENIUM. The systematic name of the fever-few. See Matricaria.

MATRIX. (Marng.) The womb. See Uterus.

MATRONALIS. (From matrona, a matron; so called because its smell is grateful to women.) The violet.

MATURANTIA. (From mature, to ripen.) Medicines which promote the sup-

puration of tumours.

MATURATION. (Maturatio; from maturo, to make ripe.) A term in surgery, signifying that process which succeeds inflammation, by which pus is collected in an abscess.

Maudlin. See Ageratum.

MAURO-MARSON. See Marrubium.

MAXILLA. (From μασσαω, to chew.) The jaw.

MAXILLA INFERIOR. Os maxillare inferius. Mandibula. inferior, or lower jaw, which, in its figure, may be compared to a horse-shoe, is at first composed of two distinct bones; but these, soon after birth, unite together at the middle of the chin, so as to form only one bone. The superior edge of this bone has, like the upper jaw, a process, called the alveolar process. This, as well as that of the upper jaw, to which it is in other respects a good deal similar, is likewise furnished with cavities for the reception of the teeth. The posterior part of the bone. on each side, rises perpendicularly into two processes, one of which is called the coronoid, and the other the conduloid, process. The first of these is the highest; it is thin and pointed; and the temporal muscle, which is attached to it, serves to elevate the jaw. The condyloid process is narrower, thicker, and shorter than the other, terminating in an oblong rounded head, which is formed for a moveable articulation with the cranium, and is received into the fore part of the fossa described in the temporal bone. In this joint there is a moveable cartilage, which, being more closely connected to the condyle than to the cavity, may be considered as belonging to the former. This moveable cartilage is connected with both the articulating surface of the temporal bone and the condyle of the jaw, by distinct ligaments arising from its edges all round. These attachments of the cartilage are strengthened, and the whole articulation secured, by an external ligament, which is common to both, and which is fixed to the temporal bone, and to the neck of the condyle. On the inner surface of the ligament, which attaches the cartilage to the temporal bone, and backwards in the cavity, is placed what is commonly called the gland of the joint; at least the ligament is there found to be much more vascular than at any other part. At the bottom of each coronoid process, on its inner part, is a The syste- foramen, or canal, which extends under See Matri- the roots of all the teeth, and terminates at the outer surface of the bone near the

shin. Each of these foramina affords a passes a branch of the fifth pair of nerves, passage to an artery, vein, and nerve, which, together with a small artery, is which send off branches to the several transmitted to the face through the exterteeth.

This bone is capable of a great many motions. The condyles, by sliding from the cavity towards the eminences on each side, bring the jaw horizontally forwards, as in the action of biting; or the condyles only may be brought forwards, while the rest of the jaw is tilted backwards, as is the case when the mouth is open. condyles may also slide alternately backwards and forwards from the cavity to the eminence, and vice versa; so that while one condyle advances, the other moves backwards, turning the body of the jaw from side to side, as in grinding the teeth. The great use of the cartilages seems to be that of securing the articulation, by adapting themselves to the different inequalities in these several motions of the jaw, and to prevent any injuries from friction. This last circumstance is of great importance where there is so much motion, and accordingly this cartilage is found in the different tribes of carnivorous animals, where there is no eminence and cavity, nor other apparatus for grinding.

The alveolar processes are formed of an external and internal plate, united together by thin bony partitions, which divide the processes at the fore part of the jaw into as many sockets as there are teeth. But, at the posterior part, where the teeth have miore than one root, each root has a distinct cell. These processes, in both jaws, begin to be formed with the teeth, accompany them in their growth, and disappear when the teeth fall. So that the loss of the one seems constantly to be attended with

the loss of the other.

MAXILLA SUPERIOR. Os maxillare superius. The superior maxillary bones constitute the most considerable portion of the upper jaw, are two in number, and generally remain distinct through life. Their figure is exceedingly irregular, and not easily to be described. On each of these bones is observed several emi-One of these is at the upper and fore-part of the bone, and, from its making part of the nose, is called the nasal process. Internally, in the inferior portion of this process, is a fossa, which, with the os unguis, forms a passage for the lachry-mal duct. Into this nasal process likewise is inserted the short round tendon of the musculus orbicularis palpebrarum. Backwards and outwards, from the root of the nasal process, the bone helps to form the lower side of the orbit, and this part is therefore called the orbitar process. hind this orbitar process, the bone forms a considerable tuberosity, and at the upper part of this tuberosity, is a channel, which is almost a complete hole. In this channel

which, together with a small artery, is transmitted to the face through the external orbitar foramen, which opens immediately under the orbit. Where the bone on each side is joined to the os mala, and helps to form the cheeks, is observed what is called the malar process. The lower and anterior parts of the bone make a kind of circular sweep, in which are the alveoli, or sockets for the teeth; this is called the ulveolar process. This alveolar process has posteriorly a considerable tuberosity on its internal surface. Above this alveolar process, and just behind the fore-teeth, is an irregular hole, called the foramen incisicum, which separating into two, and sometimes more holes, serves to transmit small arteries and veins, and a minute branch of the fifth pair of nerves, to the nostrils. There are two horizontal lamellæ behind the alveolar process, which, uniting together, form part of the roof of the mouth, and divide it from the nose. tition, being scated somewhat higher than the lower edge of the alveolar process, gives the roof of the mouth a considerable hollowness. Where the ossa maxillaria are united to each other, they project some, what forwards, leaving between them a furrow, which receives the inferior portion of the septum nasi. Each of these bones is hollow, and forms a considerable sinus under its orbiter part. This sinus, which is usually, though improperly, called antrum Highmorianum, is lined with the pi-tuitary membrane. It answers the same purposes as the other sinuses of the nose, and communicates with the nostrils by an opening, which appears to be a large one in the skeleton, but which, in the recent subject, is much smaller. In the fœtus, instead of these sinuses, an oblong depression only is observed at each side of the nostrils, nor is the tuberosity of the alveolar process then formed. On the side of the palate, in young subjects, a kind of fissure may be noticed, which seems to separate the portion of the bone which contains the dentes incisores from that which contains the dentes canini. The fissure is sometimes apparent till the sixth year, but after that period it in general wholly dis-

The ossa maxillaria not only serve to form the cheeks, but likewise the palate, nose, and orbits; and, besides their union with each other, they are connected with the greatest part of the bones of the face and cranium, viz. with the ossa nasi, ossa malarum, ossa unguis, ossa palati, os frontis, os sphenoides, and os ethmoides.

MAXILLARY ARTERIES. Arteriæ maxillariæ. These are the branches of the external carotid. The external maxillary is the fourth branch of the carotid; it proceeds anteriorly, and gives off the facial

or mental, the coronary of the lips, and the angular artery. The internal maxillary is the next branch of the carotid; it gives off the sphano maxillar, the inferior alveolar,

and the spinous artery.

MAXILLARY GLANDS. Glandulæ maxillaria. The glands so called are conglomerate, and are situated under the angles of the lower jaw. The excretory ducts of these glands are called Warthonian, after their discoverer.

MAXILLARY NERVES. Nervi maxillares. The superior and inferior maxiliary nerves are branches of the fifth pair, or tri-The former is divided into the gemini. sphæno-palatine, posterior alveolar, and the infra orbital nerve. The latter is divided into two branches, the internal lingual, and one, more properly, called the inferior maxillary.

May-lily. See Lilium convalium. May-weed. See Cotula fætida.

Mays, Indian. See Zea mays.

Maw worm. See Ascaris vermicularis.

Meadow crowfoot. See Ranunculus pratensis.

Meadow, queen of the. See U Meadow saffron. See Colchicum. See Ulmaria.

Meadow saxifrage. See Saxifraga vul-

Meadow sweet. See U'mari .

MEADOW THISTLE, ROUND LEAVED. The leaves of this plant, Cnicus oleraceus of Linnagus, are boiled, in the northern parts of Europe, and eaten as we do cab-

Measles. See Rubeola.

MEATUS AUDITORIUS EXTERNUS.

See Ear.

MEATUS AUDITORIUS INTERNUS. The internal auditory passage is a small bony canal, beginning internally by a longitudinal orifice at the posterior surface of the petrous portion of the temporal bone, running towards the vestibulum and cochlea, and there being divided into two less cavities by an eminence. The superior and smaller of these is the orifice of the aquaduct of Fallopius, which receives the portio dura of the auditory nerve: the other inferior and larger cavity is perforated by many small holes, through which the portio mollis of the auditory nerve passes into the labyrinth.

MEATUS CÆCUS. A passage in the throat to the ear, called Eustachian's tube.

MEATUS CUTICULARES. The pores of the skin.

MEATUS CYSTICUS. The gall-duct.

MEATUS URINARIUS. In women, this is situated in the vagina, immediately below the symphysis of the pubis, and behind the nymphæ. In men, it is at the end of the glans penis.

Mecca balsam. See Balsam of Gilead. Mechoacan See Mechoacanna.

MACHOACANNA, (From Mechoacan, province in Mexico, whence it is brought.) Jalappa alba. Rhabarbarum album. Mechoacam. The root of a species of convolvulus, Convolvulus Americanus, or Bryonia alba Peruviana, brought from Mexico. possesses aperient properties, and was long used as the common purge of this country, but is now wholly superseded by jalap,

MECHOACANNA NIGRA. See Jalapium. MECON. (From Mayor, buik; so named from the largeness of its head.)

paver, or poppy.

MECONIS. (From MINEW, the poppy; so called because its juice is soporiferous,

like the poppy.) The lettuce.

Meconium. (From μηκων, the poppy.) 1. The inspissated juice of the poppy. Opium. 2. The green excrementitious substance that is found in the large intestines of the fœtus.

MEDIAN NERVE. The second branch

of the brachial plexus.

MEDIAN VEINS. The situation of the veins of the arms is extremely different in most individuals. When a branch proceeds near the bend of the arm, inwardly from the basilic vein, it is termed the basilic medium; and when a vein is given off from the cephalic in the like manner, it is termed the cephalic median. When these two veins are present, they mostly unite just below the bend of the arm, and the common trunk proceeds to the cephalic vein.

The Mediastinum. MEDIANUM.

MEDIASTINUM. (Quasi in medio The membranous septum, formed by the duplicature of the pleura, that divides the cavity of the chest into two parts. It is divided into an anterior and posterior portion.

MEDIASTINUM CEREBRI. The falciform

process of the dura mater.

Medicago. (From medica.) The herb

MEDICAMENTARIA. Pharmacy, or the art of making and preparing medicines.

MEDICAMENTUM. (From medico, to

heal.) A medicine.

MEDICASTER. A false pretender to the

knowledge of medicine; the same as Quack.

MEDICINA DIETETICA. The regulation of regimen, or the non-naturals.

MEDECINA DIASOSTICA. That part of medicine which relates to preserving health.

MEDICINA GYMNASTICA. That part of medicine which relates to exercise.

MEDICINA HERMETICA. The application of chemical remedies.

That part MEDICINA PROPHYLACTICA. of medicine which relates to preserving health.

MEDICINA TRISTITIÆ. Common saffron.

MEDICINE. Any substance that is exhibited with a view to cure or allay the

violence of the disease. It is also very frequently made use of to express the healing art, when it comprehends anatomy, physi-

ology, and pathology.

MEDICINAL DAYS. Such are so called by some writers, wherein the crisis or change is expected, so as to forbid the use of medicines, in order to wait nature's effort, and therefore require all assistance of art to help forward, or prepare the humours for such a crisis: but it is most properly used for those days wherein purging, or any other evacuation, is most conveniently complied with.

MEDICINAL HOURS. Are those wherein it is supposed that medicines may be taken to the greatest advantage, commonly rec-koned in the morning fasting, about an hour before dinner, about four hours after dinner, and at going to bed; but in acute cases, the times are to be governed by the symptoms and aggravation of the distem-

MEDICINALIS. (From medicina.) Medicinal; having a power to restore health, or

remove disease. MEDINA. In Paracelsus it is a species of

MEDINENSIS VENA. (Medinensis; 30 called because it is frequent at Medina.) Dracunculus. Gordius medinensis of Linnaus. The muscular hair-worm. A very singular animal, which, in some countries, inhabits the cellular membrane between the skin and muscles. See Dracunculus.

MEDITULLIUM. (From medius, the

middle. See Diploë.

Medius venter. The middle venter is the thorax, or chest.

Medlar. See Mespilus.

MEDULLA. (Quasi in mediis ossis.) 1. The marrow. See Marrow.

2. The pith or pulp of vegetables.

3. The white substance of the brain is called medulla, or the medullary part, to distinguish it from the cortical.

4. The continuation of the brain, and in the spine, is called medullary spinalis.

MEDULLA CASSLE. The pulp of the cassia

fistularis.

MEDULLA OBLONGATA. The medullary substance, of the same use as the cerebrum, that lies within the cranium, upon the basillary process of the occipital bone. It is formed by the connection of the crura cerebri and crura cerebelli, and terminates in the spinal marrow. It has several eminences, viz. pons varioli, corpora pyramidalia, and corpora olivaria.

MEDULLA SPINALIS. Cerebrum elongatum. Aon. The spinal marrow. A continuation of the medulla oblongata, which descends into the specus vertebralis from the foramen magnum occipitale, to the third vertebra of the loins, where it termi-

nates in a number of nerves, which, from their resemblance, are called canda equina. The spinal marrow is composed, like the brain, of a cortical and medullary substance: the former is placed internally. It is covered by a continuation of the dura mater, pia mater, and tunica arachnoidea. The use of the spinal marrow is to give off, through the lateral or intervertebral foramina, thirty pairs of nerves, called cervical, dorsal, lumbar, and sacral nerves.

MEDULLARY. (.Medullaris; from medulla, marrow.) Like unto marrow.

MUDULLARY SUBSTANCE. white or internal substance of the brain is so called.

MEGALOSPLANCHNUS. (From μεγας, great, and σπλαγχνον, a bowel. Having some of the viscera enlarged, from schirrus or other

MEGRIM. A species of cephalalgia, or pain generally affecting one side of the head, towards the eye, or temple, and arising from the state of the stomach.

MEIBOMIUS'S GLANDS. glandulæ. The small glands which are situated between the conjunctive membrane of the eye and the cartilage of the eye-lid, first described by Meibomius.

MEL. See Honey.

Oxymel. "Take of MEL ACETATUM. clarified honey, two pounds; acetic acid, two pints. Boil them down to a proper consistence, in a glass vessel, over a slow fire." This preparation of honey and vinegar possesses aperient and expectorating virtues, and is given, with these intentions, in the cure of humoral asthma, and other diseases of the chest, in doses of one or two drachms. It is also employed in the form of gargle, when diluted with water.

MEL BORACIS. Honey of borax. "Take of borax, powdered, a drachm; clarified honey, an ounce. Mix." This preparation is found very useful in aphthous affections

of the fauces.

MEL DESPUMATUM. Clarified honey; See Honey.

"Take of MEL ROSE. Rose honey. red-rose petals, dried, four ounces; boiling water, three pints; clarified honey, five pounds." Macerate the rose petals in the water, for six hours, and strain; then add the honey to the strained liquor, and, by means of a water-bath, boil it down to a proper consistence. An admirable preparation for the base of various gargles and collutories. It may also be employed with advantage, mixed with extract of bark, or other medicines, to children, who have a natural disgust to medicines.

MEL SCILLE. "Take of clarified honcy, three pounds; vinegar of squills, two pints." Boil them in a glass vessel, with a slow fire, to the thickness of a syrup, nigra. Aperient, expectorant, and detergent virtues, are attributed to the honey of squills. It is given in doses of two or three drachms, along with some aromatic water, as that of cinnamon, to prevent the great nausea which it would otherwise be apt to excite. In large doses it proves emetic.

MELA. (From  $\mu\alpha\alpha$ , to search.)

probe.

MELÆNA. (From μελας, black.) The black vomit. The black disease. Hippocrates applies this name to two diseases. In the first, the patient vomits black bile, which is sometimes bloody and sour; sometimes he throws up a thin saliva; and at others a green bile, &c. In the second, the patient is as described in the article Morbus Niger.

MELAINA NOSOS. See Melana.

MELALEUCA LEUCADENDRON. The systematic name of the plant which affords the

cajeput oil. See Cajeput oil.

Melamphyllum. (From μελας, black, and φυλλου, a leaf; so named from the blackness of its leaf.) Bear's-breech. See Acanthus mollis.

MELAMPODIUM. (From Melampus, the shepherd who first used it.) Black helle-

bore. See Helleborus niger.

MELANAGOGA. (From μελας, black, and ω, to expel.) Medicines which purge aya, to expel.) off black bile.

MELANCHLORUS. (Μελαγχλωςος.) A livid colour of the skin. The black jaundice.

MELANCHOLIA. (From µExas, black, and xwan, bile; because the ancients supposed that it proceeded from a redundance of black bile,) Melancholy madness. A disease in the class neuroses, and order Vesania, of Cullen, characterised by erroneous judgment, but not merely respecting health, from imaginary perceptions or recollection, influencing the conduct, and depressing the mind with ill-grounded fears; not combined with either pyrexia or comatose affections; often appearing without dyspepsia, yet attended with costiveness, chiefly in persons of rigid fibres and torpid insensibility.

MELANOPIPER. (From μελας, black, and Black pepper. See Piтитеци, pepper.)

per nigrum.

MELANORRHIZON. (From μελας, black, and eiga, a root.) A species of hellebore with black roots.

(From μελας, black; so MELANTERIA. called because it is used for blacking leather.) Green vitriol.

MELANTHELEUM. (From μελας, black, and enace, oil.) Oil expressed from the black seeds of fennel flowers.

Melanthium. (From μελας, black; so named from its black seed.) The herb fennel flower.

MELAS. (From MELAS, black.) Vitiligo

Morphea nigra. Lepra maculosa A disease that appears upon the nigra. skin in black or brown spots, which very frequently penetrate deep, even to the bone, and do not give any pain or uneasiness. It is a disease very frequent in, and endemial to, Arabia, where it is supposed to be produced by a peculiar miasma.

MELASMA. (From µexas, black.) Melasmus. A disease that appears not unfrequently upon the tibia of aged persons, in form of a livid black spot, which, in a day or two, degenerates into a very foul

ulcer.

MELASPERMUM. (From µ6225, black, and

σπεςμα, seed.) See Melanthium.

MELCA. (From αμελρω, to milk.) Milk. food made of acidulated milk.

(From  $\mu\alpha\alpha$ , to search.) MELE.

probe.

(From Meleager, whose MELEAGRIS. sisters were fabled to have been turned into this bird.) The guinea-fowl. Also a species of frittillaria, so called because its flowers are spotted like the guinea-fowl.

MELEGETA. Meleguetta. Grains of Para-

MELEIOS. (From Melos, the island where

it is made.) A species of alum.

Melemelum. (From μωλ, honey, and μηλον, an apple; so named from its sweetness.) Paradise apple.

Meli. (Μελί.) Honey.
Meliceria. See Meliceris.
Meliceris. (From μελί, honey, and κεξος, wax.) An encysted tumour, whose contents resemble honey in consistence and appearance.

Melicraton. (From μελι, honey, and κεζαννυμι, to mix.) Hydromel. Mead. Wine

impregnated with honey.

Meligeion. (From μελ, honey.) A fatid humour, discharged from ulcers attended with a caries of the bone, of the consistenee of honey.

Melilot. See Melilotus.

MELILOTUS. (From μελι, honey, and λωτος, the lotus; so called from its smell, being like that of honey.) Lotus sylvestris. Sertula campana. Trifolium caballinum. Coroda regia. Trifolium odoratum. Common melilot. This plant, Trifolium melilotus officinalis of Linnæus, has been said to be resolvent, emollient, anodyne, and to participate of the virtues of chamomile. Its taste is unpleasant, subacrid, subsaline, but not bitter; when fresh it has scarcely any smell; in drying it acquires a pretty strong one, of the aromatic kind, but not agreeable. The principal use of melilot has been in clysters, fomentations, and other external applications.

(From μελον, an apple.) Oil MELINUM. made from the flowers of the apple-tree.

MELIPHYLLUM. (From  $\mu\omega\iota$ , honey, and quaker, a leaf; so called from the sweet smell of its leaf, or because bees gather honey from it.) Bauni, or balm. Melissa.

MELISSA. (From μελισσα, a bee, because bees gather honey from it.) Citra-Citraria. Melinum. Mellifolium. Mellitis. Cedronella. Apiastrum. Melissa citrina. Erotion. Balm. Melissa officinalis of Linnæus. A native of the southern parts of Europe, but very common in our gardens. In its recent state, it has a roughish aromatic taste, and a pleasant smell of the lemon kind. It was formerly much esteemed in nervous diseases, and very generally recommended in melancholic and hypochondriacal affections; but, in modern practice, it is only employed when prepared as tea, as a grateful diluent drink in fevers, &c.

MELISSA CALAMINTHA. The systematic name of the field catmint. See Cala-

mintha.

METISSA CITRINA. See Melissa.

MELISSA GRANDIFLORA. The systematic name of the mountain calamint. See Calamintha magno flore.

MELISSA OFFICINALIS. The systematic

name of balm. See Melissa.

MELISSA TURCICA. See Moldavica.

MELISSOPHYLLUM. (From μελισσα, baum, and φυλλον, a leaf.) Melissa, or baum. Also a species of horehound, with leaves resembling baum.

MELITIS MELISSOPHYLLUM. The systematic name of the mountain balm.

Mclyssophyllum.

MELITISMUS. (From Mell, honey.) A

linctus, prepared with honey.

MELITTOMA. (From Men, honey.) A confection made with honey. Honey-dew.

MELIZOMUM. (From MEAL, honey, and Zamos, broth.) Mead. A drink prepared with honey.

MELLAGO. (From mel, honey.) medicine which has the consistence and sweetness of honey.

MELLILOTUS. See Melilotus.

MELLINA. (From mel, honey.) Mead. A sweet drink prepared with honey.

MELLITA. (From mel, honey.) Prepa-

rations of honey.

MELO. The common melon. Musk melon. Cucumis melo of Linnaus. fruit, when ripe, has a delicious refrigerating taste, but must be eaten moderately, with pepper, or some aromatic, as all this class of fruits are obnoxious to the stomach, producing spasms and colic. The seeds possess mucilaginous qualities.

MELOCARPUS. (From MAKEY, all apple, and xxgros, fruit; from its resemblance to an apple, or its root.) The fruit of the

aristolochia.

MELOE VESICATORIUS. The Spanish fly, now called lytta.

MELON. (Mnhov.) A disorder of the eye, in which it protuberates out of the socket.

Melon, common. See Melo. Melon, musk. See Melo.

Melon, water. See Citrullus.

MELONGENA. Improperly called mala insana. Solanum pomiferum. Mad apple. The Spaniards and Italians eat it in sauce and in sweet-meats. The taste somewhat resembles citron.

MELOSIS. Μηλωσις. A term which frequently occurs in Hippocrates, Do Capit. Vulner, for that search into wounds which is made by surgeons with the specillum, or probe.

Used for the MELOTIS. MARWTIS. lesser specillum, and often for that particular instrument contrived to search or cleanse the ear with, more commonly called Auriscalpium.

The systematic MELOTHRIA PENDULA. name of the small creeping cucumber plant. The inhabitants of the West Indies pickle the berries of this plant, and use them as

we do capers. MELYSSOPHYLLUM. (From μελισσα, balm, d φυλλω, a leaf.) Mountain balm, or and φυλλοι, a leaf.) nettle. This elegant plant, Melitis melissophyllum of Linnæus, is seldom used in the present day; it is said to be of service in uterine obstructions and calculous diseases.

MEMBRANA. See Membrane.

MEMBRANA HYALOIDEA. brana arachnoidea. The transparent membrane which includes the vitreous humour of the eye.

MEMBRANA PUPILLARIS. delicate membrane, of a thin and vascular texture, and an ash colour, arising from the internal margin of the iris, and totally covering the pupil, in the fætus, before the six months.

MEMBRANA RUYSCHIANA. celebrated anatomist Ruysch discovered that the choroid membrane of the eye was composed of two laminæ. He gave the name of membrana ruyschiana to the internal lamina, leaving the old name of choroides to the external.

MEMBRANA TYMPANA. The membrane covering the cavity of the drum of the ear, and separating it from the meatus auditorius externus. It is of an oval form, convex below the middle, towards the hollow of the tympanum, and concave towards the meatus auditorius, and convex above the middle towards the meatus, and concave towards the hollow of the tympa-According to the observations of anatomists, it consists of six laminæ; the first, and most external, is a production of the epidermis, the second is a production of the skin lining the auditory passage; the third is cellular membrane, in which the vessels form an elegant net-work; the fourth is shining, thin, and transparent, arising from the periosteum of the meatus; the fifth is cellular membrane, with a plexus of vessels like the third; and the sixth lamina, which is the innermost, comes from the periosteum of the cavity of the tympanum. This membrane, thus composed of several laminæ, has lately been discovered to possess muscular fibres.

MEMBRANALOGIA. (From membrana, a membrane, and λογος, a discourse.)
Membranology. The doctrine of the com-

mon integuments and membranes.

MEMBRANE. Membrana. A thin expanded substance, composed of cellular texture, whose elastic fibres are so arranged and woven together, as to allow of great pliability. The membranes of the body are various, as the skin, peritoneum, pleura, dura mater, &c. &c.

MEMBRANOSUS. See Tensor vaginæ fe-

moris.

MEMBRANUS. See Tensor vagina femo-

MEMBRIE OS. See Occipital bonc. Menagogues. See Emmenagogues.

MENDOSUS. (From mendax, counterfeit,)
This term is used, by some, in the same
sense as spurius, or illegitimus; Mendosa
Coste, false or spurious ribs; Mendosa Sutura, the squamous suture, in the skull, or

bastard suture.

MENINGOPHILAX. (From μνηγέ, a membrane, and φυλασσω, to guard.) An instrument to guard the membranes of the brain, while the bone is cut, or rasped, after the

operation of the trepan.

MENINX. (From µn, to remain.) The Greek term for the membranes enveloping the brain. See Dura mater and Pia mater.

MENINX DURA. See Dura mater. MENINX PIA. See Pia mater.

MENISPERMUM COCCULES. The systematic name of the plant the berries of which are well known by the name of Cocculus indus. Indian berries, or Indian cockles Whilst green, they are used by the Indians to catch fish, which they have the power of intoxicating, and killing. In the same manner they catch birds, making the berry into a paste, forming it into small seeds, and putting these in places where they frequent.

MENORRHAGIA. (From μενια, the menses, and ρεγνυμ, to break out.) Hæmorrhagia uterina. Flooding. An immoderate flow of the menses. A genus of disease in the class pyrexia, and order hæmorrhagiα, of Cullen, characterized by pains in the back, loins, belly, similar to those of labour, attended with a preternatural flux of blood from the vagina, more copious than natural. He distinguishes six

species:--

1. Menorrhagia rubra, proper; from

women neither with child nor in childbirth.

2. Menorrhagia alba, serous; the fluor albus See Leucorrhaa.

3. Menorrhagia vitiorum, from some local disease

4. Menorrhagia lochialis, from women after delivery. See Lochia.

5. Menorrhagia abortus. See Abortion.
6. Menorrhagia nabothi, when there is a serous discharge from the vagina in preg-

nant women.

This disease seldom occurs before the age of puberty, and is often an attendant on pregnancy. It is in general a very dangerous disease, more particularly if it occur at the latter period, as it is then often so rapid and violent as to destroy the female in a very short time, where proper means are not soon adopted. Abortions often give rise to floodings, and at any period of pregnancy, but usually before the fifth month than at any other time. Moles, in consequence of an imperfect conception, at length become detached, and sometimes give rise to a considerable degree of hamorrhage.

The causes which most frequently give rise to floodings are, violent exertions of strength, sudden surprises and frights, violent fits and passion, great uncasiness of mind, uncommon longings during pregnancy, over fullness of blood, profuse evacuations, general weakness of the system, external injuries, as blows and bruises, and the death of the child, in consequence of which the placenta becomes partially or wholly detached from the uterus, leaving the mouths of the vessels of the latter, which anasto-mosed with those of the latter, perfectly open. It is necessary to distinguish be-tween an approaching miscarriage and a common flooding, which may be readily done by inquiring whether or not the hamorrhage has proceeded from any evident cause, and whether it flows gently, or is accompanied with unusual pains. The former usually arises from some fright, surprise, or accident, and does not flow gently and regularly; but bursts out of a sudden and again stops all at once, and also is attended with severe pains in the back and the bottom of the belly; whereas the latter is marked with no such occurrence. The further a woman is advanced in pregnancy, the greater will be the danger if floodings take place, as the mouths of the vessels are much enlarged during the last stage of pregnancy, and of course a vast quantity will be discharged in a short space of time.

Mensa. The second lobe of the liver was so called by the ancients.

Menses. (From mensis, a month.)

Menses cessantes. The menses departing.

Menses deficientes. Menses defective or suppressed. The amenorrhoa of Cullen.

MENSES IMMODICE. The menorrhagia rubra of Cullen.

Menses, immoderate flow of the. Se Menorrhagia.

Menses, interruption of. See Amennor-han.

Menses, retention of. See Catumenia.

Menses rithosophicus, A philosophical, or chymical month. According to some, it is three days and nights; others say it is ten; and there are who reckon it

to be thirty or forty days.

MENSTRUATION. From the uterus of every healthy woman who is not pregnant, or who does not give suck, there is a discharge of blood at certain periods, from the time of puberty to the approach of old age; and, from the periods or returns of this discharge, it is called Menstruation. There are several exceptions to this definition. It is said that some women never menstruate; some menstruate while they continue to give suck; and others are said to menstruate during pregnancy; some are said to menstruate in early infancy, and others in old age; but such discharges, Dr. Denman is of opinion, may, with more propriety, be called morbid, or symptomatic: yet the definition is generally

At whatever time of life this discharge comes on, a woman is said to be at puberty: though of this state it is a consequence, and not a cause The early or late appearance of the menses may depend upon the climate, the constitution, the delicacy or hardness of hving, and upon the manners of those with whom young women converse. In Greece, and other hot countries, girls begin to menstruate at eight, nine, and ten years of age; but, advancing to the northern climes, there is a gradual protraction of the time till we come to Lapland, where women do not menstruate till they arrive at maturer age, and then in small quantities, at long intervals, and sometimes only in the summer. But, if they do not menstruate according to the genius of the country, it is said they suffer equal inconveniences as in warmer climates, where the quantity discharged is much greater, and the periods shorter. In this country, girls begin to menstruate from the fourteenth to the eighteenth year of their age, and sometimes at a later period, without any signs of the disease; but if they are luxuriously educated, sleeping upon down beds, and sitting in hot rooms, menstruation usually commences at a more early pe-

Many changes in the constitution and appearance of women are produced at the time of their first beginning to menstruate.

Their complexion is improved, their countenance is more expressive and animated, their attitudes graceful, and their conversation more intelligent and agreeable; the tone of their voice becomes more harmonious, their whole frame, but particularly their breasts, are expanded and enlarge, and their minds are no longer engaged in childish pursuits and amusements.

Some girls begin to menstruate without any preceding indisposition; but there are generally appearances or symptoms which indicate the change that is about to take These are usually more severe at the first than in the succeeding periods: and they are similar to those produced by uterine irritation from other causes, as pains in the back and inferior extremities, complaints of the viscera, with various hysteric and nervous affections. These commence with the first disposition to menstruate, and continue till the discharge comes on, when they abate, or disappear, returning, however, with considerable violence in some women, at every period during life. The quantity of blood discharged at each evacuation depends upon the climate, constitution, and manner of living; but it varies in different women in the same climate, or in the same woman at different periods; in this country it amounts to about five or six ounces.

There is also a great difference in the time required for the completion of each period of menstruation. In some women the discharge returns precisely to a day, or an hour, and in others there is a variation of several days, without inconvenience. In some it is finished in a few hours, and in others it continues from one to ten days; but the intermediate time, from three to

six days, is most usual.

There has been an opinion, probably derived from the Jewish legislator, afterwards adopted by the Arabian physicians, and credited in other countries, that the menstruous blood possessed some peculiar malignant properties. The severe regulations which have been made in some countries for the conduct of women, at the time of menstruation: - the expression used, Isaiah, chap. xxx. and in Ezekiel ;-the disposal of the blood discharged, or of any thing contaminated with it:-the complaints of women attributed to its retention; -and the effects enumerated by grave writers, indicate the most dreadful apprehensions of its baneful influence. Under peculiar circuinstances of health, or states of the uterus, or in hot climates, if the evacuation be slowly made, the menstruous blood may become more acrimonious or offensive than the common mass, or any other secretion from it; but in this country and age no malignity is suspected, the menstruous woman mixes in society as at all other

times, and there is no reasan for thinking otherwise than that this discharge is of the most inoffensive nature.

At the approach of old age, women cease to menstruate; but the time of cessation is commonly regulated by the original early or late appearances of the menses. With those who began to menstruate at ten or twelve years of age, the discharge will often cease before they arrive at forty; but if the first appearance was protracted to sixteen or eighteen years of age, independently of disease, such women may continue to menstruate till they have passed the fiftieth, or even approach the sixtieth year of their age. But the most frequent time of the cessation of the menses, in this country, is between the forty-fourth and forty-eighth year; after which women never bear children. By this constitutional regulation of the menses, the propagation of the species is in every country confined to the most vigorous part of life; and had it been otherwise, children might have become parents, and old women might have had children, when they were unable to supply them with proper or sufficient nourishment. See Catamenia.

MENSTRUUM. Solvent. All liquors are so called which are used as dissolvents, or to extract the virtues or ingredients by infusion, decoction, &c. The principal menstrua, made use of in Pharmacy, are water, vinous spirits, oils, acid, and alkaline liquors. Water is the menstruum of all salts, of vegetable gums, and of animal jellies. Of the first it dissolves only a determinate quantity, though of one kind of salt more than of another; and being thus saturated, leaves any additional quantity of the same salt untouched. It is never saturated with the two latter, but unites readily with any proportion of them, forming, with different quantities, liquors of different consistences. It takes up like-wise, when assisted by trituration, the vegetable gummy resins, as ammoniacum and myrrh; the solutions of which, though imperfect, that is, not transparent, but turbid and of a milky hue, are nevertheless applicable to valuable purposes in medicine. Rectified spirit of wine is the menstruum of the essential oils and resins of vegetables; of the pure distilled oils of animals, and of soaps, though it does not act upon the expressed oil and fixed alkaline salt, of which soap is composed. Hence, if soap contains any superfluous quantity of either the oil or salt, it may, by means of this menstruum, be excellently purified therefrom. It dissolves, by the assistance of heat, volatile alkaline salts; and more readily the neutral ones, composed either of fixed alkali and the acetous acid, as the sal diureticus, or of volatile

alkali and the nitrous acid. Oils dissolve vegetable resins and balsams, wax, animal fats, mineral bitumens, sulphur, and certain metallic substances, particularly lead. The expressed oils are, for most of these bodies, more powerful menstrua than those obtained by distillation; as the former are more capable of sustaining, without injury, a strong heat, which is in most cases necessary to enable them to act. All acids dissolve alkaline salts, alkaline earths, and metallic substances. The different acids differ greatly in their action upon these last: one dissolving some particular metals, and another others. The vegetable acids dissolve a considerable quantity of zinc, iron, copper, and tin; and extract so much from the metallic part of the antimony as to become powerfully emetic; they likewise dissolve lead, if previously calcined by fire; but more copiously if corroded by their steam. The marine acid dissolves zinc, iron, and copper; and though it scarce acts on any other metallic substance in the common way of making solutions, may nevertheless be artfully combined with them all, except gold. The corrosive sublimate, and antimonial caustic of the shops, are combinations of it with mercury and the metallic part of antimony, effected by applying the acid, in the form of fume, to the subjects, at the same time strongly heated. The nitrous acid is the common menstruum of all metallic substances, except gold and the antimonial semi-metal, which are soluble only in a mixture of the nitrous and marine. The vitriolic acid easily dissolves zinc, iron, and copper; and may be made to corrode, or imperfectly dissolve, most of the other metals. Alkaline lixivia dissolve oils, resinous substances, and sulphur. Their power is greatly promoted by the addition of quick-lime, instances of which occur in the preparation of soap and in the common caustic. Thus assisted, they reduce the flesh, bones, and other solid parts of animals, into a gelatinous matter. Solutions made in water and spirit of wine possess the virtue of the body dissolved; whilst oils generally slicathe its activity, and acids and alkalies vary its quality. Hence watery and spiritous liquors are the proper menstrua of the native virtues of vegetable and animal matters. Most of the foregoing solutions are easily effected, by pouring the menstruum on the body to be dissolved, and suffering them to stand together for some time, exposed to a suitable warmth. A strong heat is generally requisite to enable oils and alkaline liquors to perform their office; nor will acids act on some metallic bodies without its assistance. The action of watery and spirituous menstrua is likewise expedited by a moderate heat, though the quantity which

they afterwards keep dissolved, is not, as some suppose, by this means increased. All that heat occasions these to take up, more than they would do in a longer time in the cold, will, when the heat ceases, subside again. The action of acids on the bodies which they dissolve, is generally accompanied with heat, effervescence, and a copious discharge of fumes. The fumes which arise during the dissolution of some metals, in the vitriolic acid, prove inflammable; hence, in the preparation of the artificial vitriols of iron and zinc, the operator ought to be careful, especially where the solution is made in a narrow mouthed vessel, lest, by the imprudent approach of a candle, the exhaling vapour be set on fire. There is another species of solution in which the moisture of air is the menstruum. Fixed alkaline salts, and those of the neutral kind, composed of alkaline salts and the vegetable acids, or of alkaline earths, and any acid except the vitriolic, and some metallic salts, on being exposed for some time to a moist air, gradually attract its liumidity, and at length become liquid. Some substances, not dissoluble in water in its grosser form, as the butter of antimony, are easily liquified by this slow action of the aërial moisture. This process is termed Deliquation. The cause of solution assigned by some naturalists, namely, the admission of the fine particles of one body into the pores of another, whose figure fits them for their reception, is not just, or adequate, but hypothetical and ill-presumed; since it is found that some bodies will dissolve their own quantity of others, as water does of Epsom salt, alkohol of essential oils, mercury of metals, one metal of another, &c. whereas the sum of the pores or vacuities of every body must be necessarily less than the body itself, and consequently those pores cannot receive a quantity of matter equal to the body wherein they reside.

How a menstruum can suspend bodies much heavier than itself, which very often happens, may be conceived, by considering, that the parts of no fluids can be so easily separated, but they will a little resist or retard the descent of any heavy bodies through them: and that this resistance is, ceteris paribus, still proportional to the surface of the descending bodies. But the surface of bodies do by no means increase or decrease in the same proportion as their solidities do: for the solidity increases as the cube, but the surface only as the square of the diameter; wherefore it is plain, very small bodies will have much larger surfaces, in proportion to their solid contents, than larger bodies will, and consequently, when grown exceeding small, may easily be buoyed up in the liquor.

MENTAGRA. (From mentum, the chin,

and ayea, a prey.) Impetigo. An eruption about the chin, forming a tenacious crust, like that on scald heads.

MENTASTRUM. (Dim. of mentha, mint.) The red water-mint. See Mentha aqua-

MENTHA. (From Minthe, the harlot who was changed into this herb.) Hidyosnus. The name of a genus of plants in the Linnæan system. Class, Didynamia. Order, Gymnospermia. Mant.

MENTHA AQUATICA. Mentastrum. Si-symbrium menthastrum. Mentha rotundifolia palustris. Water-mint. This plant is frequent in moist meadows, marshes, and on the banks of rivers. It is less agreeable than the spear mint, and in taste bitterer and more pungent. It may be used with the same intentions as the spearmint, to which, however, it is much inferior.

MENTHA CATARIA. Menthu felina. Herba felis. Calamintha. Nepetella. Nep, or cat-

mint. See Nepeta.

MENTHA CERVINA. The systematic name of the hart's penny-royal. See Pulegium cer-

MENTHA CHISPA. Colymbifera minor. The achillæa ageratum. This species of mentha has a strong and fragrant smell, its taste is warm, aromatic, and slightly bitter. In flatulences of the primæ viæ, hypochondriacal, and hysterical affections, it is given with advantage.

MENTIIA PIPERITA. The systematic and pharmacopæial name of peppermint. Mentha piperitis. Mentha piperita of Linnæus :- floribus capitatis, foliis oratis petiolatis, staminibus corolla brevioribus. The spontaneous growth of this plant is said to be peculiar to Britain. It has a more penetrating smell than any of the other mints; a strong pungent taste, glowing like pepper, sinking, as it were, into the tongue, and followed by a sense of coolness. The stomachic, antispasmodic, and carminative properties of peppermint, render it useful in flatulent cholics, hysterical affections, retchings, and other dispeptic symptoms, acting as a cordial, and often producing an immediate relief. Its officinal preparations are an essential oil, a simple water, and a spirit.

MENTHA PIPERITIS. See Mentha pipe-

The systematic MENTHA PULEGIUM. name of the pennyroyal. See Pulegium. MENTHA SARACENICA. See Balsamita

MENTHA SATIVA. See Mentha viridis. MENTHA SPICATA. Hart-mint, and com-Mentha vulgaris. See mon spear-mint. Mentha viridis.

MENTHA VIRIDIS. Spear-mint. Called also Mentha vulgaris. Mentha spicata. Mentha viridis of Linnaus :- spicio oblongis, foliis lanceolatis nudis serratis ses-

3 R \*

silibus, staminibus corolla longioribus. plant grows wild in many parts of England. It is not so warm to the taste as peppermint, but has a more agreeable flavour, and is therefore preferred for culinary purposes. Its medicinal qualities are, similar to those of peppermint; but the different preparations of the former, though more pleasant, are, perhaps, less effica-cious. The officinal preparations of spearmint are, an essential oil, a conserve, a simple water, and a spirit.

MENTI LEVATOR. See Levator labii in-

ferioris.

MENTULA. (From matah, a staff, Heb.)

The penis.

MENTULAGRA. (From mentula, the penis, and ayex, a prey.) A disorder of the penis, induced by a contraction of the erectores musculi, and causing impo-

MENYANTHES. The name of a genus of plants in the Linnæan system. Class,

Pentandria. Order, Monogynia.

MENYANTHES TRIFOLIATA. The systematic name of the buckbean. See Trifolium paludosum.

Methetic air. See Nitrogen.

MEPHITIS. (From mephuhith, a blast. Syr.) A poisonous exhalation. See Contagion.

MERCURIALIS. (From Mercurius, its inventor.) 1. The name of a genus of plants in the Linnæan system. Class, Dioe-

cia. Order, Emeandria.

2. The phartnacopæial name of the French mercury. Mercurialis annua of Linnæus. The leaves of this plant have no remarkable smell, and very little taste. It is ranked among the emollient oleraceous herbs, and is said to be gently aperient. Their principal use has been in clys-

MERCURIUS EMETICUS FLAVOS. See Ilydrargyrus vitriolatus.

See

MERCURIUS MORTIS.

MERCURIUS PRECIPITATUS ALBUS.

Hydrargyrus pracipitatus albus. MERCURIUS PRÆCIPITATUS DULCIS.

Submuria hydrargyri.

MERCURIUS PRÆCIPITATUS RUBER.

Nitrico oxydum hydrargyri.
MERCURIUS VITE. The mercury of life. Pulvis angelicus. Mercurius mortis. Algarothi pulvis. An oxyd, of antimony, formerly preferred to the vitrum antimonii, for making of emetic tartar.

MERCURY. Hydrargyrus. Mercurins. A metal found in five different states in nature. 1. Native, (native mercury,) adhering in small globules to the surface of cinnabar ores, or scattered through the crevices, or over the surfaces of different kinds of stones. 2. It is found united to silver, in the ore called amalgam of silver, or native amalgam. This ore exhibits thin plates, or grains; it sometimes crystallizes in cubes, parallelopipeds, or pyramids. Its colour is of a silver white, or grey; its lustre is considerably metallic. Combined with sulphur it constitutes native cinnabar, or sulphuret of mercury. This ore is the most common. It is frequently found in veins, and sometime crystallized in tetrahedra, or three-sided pyramids. Its colour is red. Its streak metallic. 3.4. Mercury, united either to muriatic or sulphuric acid, forms the ore called horn quicksilver, or corneous mercury. These ores are, in general, semi-transparent, of a grey or white colour, sometimes crystallized, but more frequently in grains. 5. United to oxygen it constitutes the ore called native oxyd of Mercurial ores particularly mercury. abound in Spain, Hungary, China, and South America.

Properties .- Mercury, or quicksilver, is the only one of the metals that remains fluid at the ordinary temperature of the atmosphere, but when its temperature is reduced to - 40° Fahr. it assumes a solid form. This is a degree of cold, however, that only occurs in high northern latitudes, and, in our climate, mercury cannot be exhibited in a solid state, but by means of artificial cold. When rendered solid, it possesses both ductility and malleability. It crystallizes in octahedra, and contracts

strongly during congelation. It is divisible in very small globules. It presents a convex appearance in vessels to which it has little attraction, but is concave in those to which it does adhere. becomes electric and phosphorescent by rubbing upon glass, and by agitation in a vacuum. It is a very good conductor of caloric, of electricty, and of Galvanism. The specific gravity of mercury is 13.563. Although fluid, its opacity is equal to that of any other metal, and its surface, when clean, has considerable lustre. Its colour is white, similar to silver. Exposed to the temperature of 600° Fahr, it is volatilized. When agitated in the air, especially in contact with viscous fluids, it becomes converted into a black oxyd. At a temperature nearly the same as that at which it boils, it absorbs about 14 or 16 per cent. of oxygen, and then becomes changed into a red crystallizable oxyd, which is spontaneously reducible by caloric and light at a higher temperature. The greater number of the acids act upon mercury, or are at least capable of combining with its oxyds. It combines with sulphur by trituration, but more intimately by heat. It is acted on by the alkaline sulphurets. It combines with many of the metals; these compounds are brittle, or soft, when the mercury is in large proportion. There is a slight union between mercury and phosphorus. It does not unite with carbon, or the earths.

Method of obtaining Mercury.—Mercury may be obtained pure by decomposing ciunabar, by means of iron filings. For that purpose, take two parts of red sulphuret of mercury (cinnabar), reduce it to powder, and max it with one of iron filings, put the mixture into a stone retort, direct the neck of it into a bottle, or receiver, filled with water, and apply heat. The mercury will then be obtained in a state of

purity.

In this process, the sulphuret of mercury, which consists of sulphur and mercury, is heated in contact with iron, the sulphur quits the mercury and unites to the iron, and the mercury becomes disengaged; the residue in the retort is a sulphuret of iron.

Mercury is a very useful article both in the cure of diseases and the arts. There is scarcely a disease against which some of its preparations are not exhibited; and over the venereal disease it possesses a specific power. It is considered to have first gained repute in curing this disease, from the good effects it produced in eruptive diseases. In the times immediately following the venereal disease, practitioners only attempted to employ this remedy with timorous caution, so that, of several of their formulæ, mercury scarcely composed a fourth part, and few cures were On the other hand, empiries, who noticed the little efficacy of these small doses, ran into the opposite extreme,

and exhibited mercury in such large quantities, and with such little care, that most of their patients became suddenly attacked with the most violent salivations, attended with dangerous consequences. From these two very opposite modes of practice, there originated such uncertainty respecting what could be expected from mercury, and such fears of the consequences which might result from its employment, that every plan was eagerly adopted, which offered the least chance of cure without having recourse to this mineral. A medicine, however, so powerful, and whose salutary effects were seen, by attentive practitioners, amid all its inconveniences, could not sink into oblivion. After efforts had been made to discover a substitute for it, and it was seen how little confidence those means deserved on which the highest praises had been lavished, the attempts to discover its utility were renewed. A medium was pursued, between the too timid methods of those physicians who had first administered it, and the inconsiderate boldness of the empiries. Thus the causes from which both parties failed were avoided; the character of the medicine was revived in a more durable way, and from this period its reputation has always been maintained.

It was about this epoch that mercury began to be internally given; hitherto it had only been externally employed, which was done in three manners. The first was in the form of limiment, or ointment; the second as a plaster; and the third as a fumigation. Of the three methods just described, only the first is at present much in use, and even this is very much altered. Mercurial plasters are now only used as topical discutient applications to tumours and indurations. Fumigations, as anciently managed, were liable to many objections, particularly from its not being possible to regulate the quantity of mercury to be used, and from the effect of the vapour on the organs of respiration frequently occasioning trembling, palsies, &c. Frictions with ointment have always been regarded as the most efficacious mode of administer-

ing mercury.

Mercury is carried into the constitution in the same way as other substances, either by being absorbed from the surface of the body, or that of the alimentary canal. It cannot, however, in all cases, be taken into the constitution in both ways, for sometimes the absorbents of the skin will not readily receive it; at least no effect is produced, either on the disease or constititution, from this mode of application. On the other hand, the internal absorbents will, sometimes, not take up the medicine. or, at least, no effect is produced either on the disease or constitution. In many persons, the bowels can hardly bear mercury at all; and it should then be given in the mildest form possible, conjoined with such medicines as will lessen or correct its violent effects, although not its specific ones, on the constitution. When mercury can be thrown into the constitution with propriety, by the external method, it is preferable to the internal plan; because the skin is not nearly so essential to life as the stomach, and is therefore in itself capable of bearing much more than the stomach. The constitution is also less injured. Many courses of mercury would kill the putient if the medicine were only given internally, because it proves hurtful to the stomach and intestines, when given in any form, or joined with the greatest correctors.

Mercury has two effects; one as a stimulus on the constitution and particular parts, the other as a specific on a discased action on the whole body, or of parts. The latter action can only be compared.

puted by the disease disappearing.

In giving mercury in the venereal disease, the first attention should be to the quantity, and its visible effects in a given time; which, when brought to a proper pitch, are only to be kept up, and the decline of the disease to be watched; for by this we judge of the invisible or specific effects of the medicine, and know what variation in the quantity may be necessary. The visible effects of mercury affect either the whole constitution, or some parts capable of secretion. In the first, it produces universal irritability, making it more sus-ceptible of all impressions. It quickens the pulse, increases its hardness, and oc-casions a kind of temporary fever. In some constitutions, it operates like a poison. In some it produces a kind of hectic fever; but such effects commonly diminish on the patient becoming accustomed to the medicine.

Mercury often produces pains, like those of rheumatism, and nodes of a scrophulous nature. The quantity of mercury to be thrown in for the cure of any venereal complaint, must be proportioned to the violence of the diseasc. A small quantity, used quickly, will have equal effects to those of a large one employed slowly; but if these effects are merely local, that is, upon the glands of the mouth, the constitution at large not being equally stimulated, the effects upon the diseased parts must be less, which may be known by the local disease not giving way in proportion to the effects of mercury on some particular part. If it be given in very small quantities, and increased gradually, so as to steal insensibly on the constitution, a vast quantity at a time may at length be thrown in without any visble effects at all.

The constitution, or parts, are more susceptible of mercury at first than after-

wards.

Mercury occasionally attacks the bowels, and causes violent purging, even of blood.

This effect is remedied by intermitting the use of the medicine, and exhibiting At other times, it is suddenly determined to the mouth, and produces inflammation, ulceration, and an excessive flow or saliva. To obtain relief in this circumstance, purgatives, nitre, sulphur, gum-arabic, lime-water, camphor, bark, kali-sulphuratum, blisters, &c. have been advised. Mr. Pearson, however, does not place much confidence in the efficacy of such means; and, the mercury being discontinued for a time, he recommends the patient to be freely exposed to a cold air, with the occasional use of cathartics, mineral acids, Peruvian bark, and the assiduous application of astringent gargles. The most material objection (says Mr. Pearson,) which I foresec against the method of treatment I have recommended, is the hazard to which the patient will be exposed of having the saliva suddenly checked, and of suffering some other disease in consequence of it.

The hasty suppression of a ptyalism may be followed by serious inconveniencies, as violent pains, vomiting, and general con-

vulsions.

Cold liquids taken into the stomach, or exposure of the body to the cold air, must be guarded against during a course of mercury. Should a suppression of the ptyalism take place, from any act of indiscretion, a quick introduction of mercury should be had recourse to, with the occasional use of the warm bath.

Mercury, when it falls on the mouth, sometimes produces inflammation, which now and then terminates in mortification. The ordinary operation of mercury does not permanently injure the constitution; but, occasionally, the impairment is very material; mercury may even produce local diseases, and retard the cure of chancres, buboes, and certain effects of the lues venerea, after the poison has been destroyed. Occasionally, mercury acts on the system as a poison, quite unconnected with its agency as a remedy, and neither proportionate to the inflammation of the mouth nor actual quantity of the mineral ab-Mr Pearson has termed this sorbed. morbid state of the system erethismus; it is characterised by great depression of strength, a sense of anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small, quick, and sometimes intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, and neither the natural or vital functions are much dis-When this effect of mercury takes place, the use of mercury should be discontinued, whatever may be the stage, extent, or violence of the venereal disease. The patient should be exposed to a dry and cool air, in such a way as not to give

fatigue; in this way the patient will often recover in ten or fourteen days. In the · carly stage, the erethismus may often be averted by leaving off the mercury and giving campnor mixture with volatile alkali. Occasionally, the use of mercury brings on a peculiar eruption, which has received the names of mercurial rash, eczema mercuriale, lepra mercurialis, mercurial disease, and erythema mercuriale.

In order that mercury should act on the human body, it is necessary that it should be oxydised, or combined with an acid. The mercury contained in the unguentum hydrargyri is an oxyde. The metal, however, in the mercural ointment, is the most simple and least combined form of all its preparations, and hence, (says Mr. S. Cooper,) it not only operates with more mildness on the system, but with more specific effect on the disease. Various salts of mercury operate more quickly when given internally than mercurial frictions; but few practitioners of the present day confide in the internal use of mercury alone; particularly when the venereal virus has produced effects in consequence of absorption. Rubbing in mercurial ointment is the mode of affecting the system with mercury in the present day; and, as a substitute for this mode of applying mercury, Mr. Abernethy recommends the mercurial fumigation, where the patient has not strength to rub in ointment, and whose bowels will not bear the internal exhibition

The preparations of mercury now in use

1. Nitrico-oxydum hydrargyri.

2. Oxydum hydrargyri cinercum.

3. Oxydum hydrargyri rubrum. 4. Oxy-murias hydrargyri.

5. Submurias hydrargyri.

6. Sulphuretum hydra: gyri rubrum.

7. Hydrargyrus cum creta.

8. Hydrargyrus precipitatus albus.

9. Hydrargyrus perificetus.
Mercury, dug's. See Cynocrambe

Mercury, English. See Bonus henricus. Mercury, French. See Mercurialis.

Mercoley, From μερος, a part, and βαλανείον, a buth.) A partitibath.

MEROCELE. (From μερος, the thigh,

and anan, a tumour.) A femoral hernia. See Hernia.

Minnen. (Magos.) The thigh.

Manus. Appled to several things in the same sense as genuine, or unadulterated, as merum vinum, neat wine.

Massarum. (From peroc, the middle,

and agaix, the belly.) The mesentery.

MISEMBRY ANTHEUM CHRYSTALLINUM. The juice of this plant, in a dose of four spoonfuls every two hours, it is asserted has removed an obstinate spasmodic affection of the neck of the bladder, which would not yield to other remedics.

MESENTERIC. Meseraic. Belonging to the mesentery. See Mesentery.

MESENTERIC ARTERIES. Arteriæ mesentericæ. Two branches of the sorta in the abdomen are so called. The superior mesenteric is the second branch; it is distributed upon the mesentery, and gives off the superior or right colic artery. The inferior mesenteric is the fifth branch of the aorta; it sends off the internal hamorrhoidal,

MESENTERIC GLANDS. mesenterica. These are conglobate, and are situated here and there in the cellular membrane of the mesentery. The chyle from the intestines passes through these glands to the thoracic duct.

MESENTERIC PLEXUS OF NERVES. Nervorum plexus mesentericus. The superior, middle, and lower mesenteric plexuses of nerves are formed by the branches of the

great intercostal nerves.

MESENTERIC VEINS. Venæ mesenterice. They all run into one trunk, that evacuates its blood into the vena porta-See Vena portæ.

MESENTERITIS. (From μεσενθεριον, the mesentery.) An inflammation of the mesentery. A species of peritonitis of Cul-

MESENTERY. (Mesenterium; from A membrane in the cavity of the abdomen, attached to the vertebræ of the loins, and to which the intestines adhere. It is formed of a duplicature of the peritonæum, and contains within it, adipose membrane, lacteals, lymphatics, lacteal glands, mesen-teric arteries, veins, and nerves. Its use is to sustain the intestines in such a manner that they possess noth mobility and firmness; to support and conduct with safety the blood-vessels, lacteals, and nerves; to fix the glands, and give an external coat to the intestines.

It consists of three parts: one uniting the small intestines, which receives the proper name of mesentery; another connecting the great intestines, termed mesocolon; and a third attached to the rectum. termed mesorectum.

MESERAIC. The same as mesenteric.

Muserion. See Mezerium.

Messue A disorder of the liver, mentioned by Avicenna, accompanied with a sense of heaviness, tumour, inflammation,

pungent pain, and blackness of the tongue.
MESOCOLON (From 12005, the middle, and nanov, the colon.) The portion of the mesentery to which the colon is attached. The mesentery and mesocolon are the most important of all the productions of the peritonoum. In the pelvis, the peritonaum spreads itself shortly before the rectum. But where that intestine Lecomes loose, and forms the semilunar curve, the peritonaum there rises consi-

derably from the middle iliac vessels, and region of the psoas muscle, double, and with a figure adapted for receiving the hollow colon. But above, on the left side, the colon is connected with almost no intermediate loose production to the peritonæum, spread upon the psoas muscle, as high as the spleen, where this part of the nigh as the spheet, make the pare periton aum, which gave a coat to the colon, being extended under the spleen, receives and sustains that viscus in a hol-

low superior recess. Afterwards the peritonæum, from the left kidney, from the interval between the kidneys, from the large vessels, and from the right kidney, emerges forwards under the pancreas, and forms a broad and sufficiently long continuous production, called the transverse mesocolon, which, like a partition, divides the upper part of the abdomen, containing the stomach, liver, spleen, and pancreas, from the lower part. The lower plate of this transverse production is continued singly from the right mesocolon to the left, and serves as an external coat to a pretty large portion of the liver, and descending part of the duodenum. But the upper plate, less simple in the course, departs from the lumbar peritonænum at the kidney, and region of the vena cava, farther to the right than the duodenum, to which it gives an external membrane, not quite to the valve of the pylorus; and beyond this intestine, and beyond the colon, it is joined with the lower plate, so that a large part of the duodenum lies within the cavity of the mesocolon. Afterwards, in the region of the liver, the mesocolon is inflected, and descending over the kidney of the same side much shorter, it includes the right of the colon, as far as the intestinum cæcum, which rests upon the iliac muscle and the appendix, which is provided with a peculiar long curved mesentery. There the mesocolon terminates, almost at the bifurcation of the aorta.

The whole of the mesocolon and of the mesentery is hollow, so that the air may be forced in between its two laminæ, in such a manner as to expand them into a bag. At the place where it sustains the colon, and also from part of the intestinum rectum, the mesocolon, continuous with the outer membrane of the intestine, forms itself into small slender bags, resembling the omentum, for the most part in pairs, with their loose extremities thicker and bifid, and capable of admitting air blown in between the plates of the mesocolon.

Mesocranium. (From μεσος, the middle, and κζανίον, the skull.) The crown of

tine head, or vertex.

MESOGASTRIUM. (From peros, the mid-dle, and pasng, the stomach.) The substance on the concave part of the stomach, which attaches itself to the adjacent parts.

Mesoglossus. (From peros, the middle, and alwora, the tongue.) A muscle inserted in the middle of the tongue.

MESOMERIA. (From μεσος, the middle, and μεσος, the thigh.) The parts between

the thighs.

MESOMPHALIUM. (From μεσος, the middle, and ompanos, the navel.) The middle of the navel.

(From peros, the mid. MESOPHRYUM. dle, and oqqua, the eyebrows.) The part between the eyebrows.

MESOPLEURUM. (From peros, the middle, and masugor, a rib.) The space or mus-

cles between the ribs.

MESORECTUM. (From Mesos, the middle, and rectum, the straight gut.) The portion of peritonæum which connects the rectum to the pelvis.

MESOTHENAR. (From peros, the middle, and bevae, the palm of the hand.) A muscle situated in the middle of the palm of the hand.

MESPILUS. (Οτι εν μεσος πιλος, because it has a cap or crown in the middle of it.) The name of a genus of plants in the Linnaan system. Class, Icosandria.

Order, Pentagynia.

2. The pharmocopæial name of the medlar. This fruit, and also its seeds, medlar. have been used medicinally. The tree which bears them is the Mespilus ger-manica of Linnæus. The immature fruit is serviceable in checking diarrhoas; and the seeds were formerly esteemed in allaying the pain attendant on nephritic diseases.

MESPILUS GERMANICA. The systematic name of the medlar-tree. See Mespilus.

METABASIS. (From μεταβαινώ, to digress.) Metabole. A change of remedy. of practice, or disease; or any change from one thing to another, either in the curative indications, or the symptoms of a distemper.

METABOLE. See Metabasis.

METACARPAL BONES. The five longitudinal bones that are situated between the wrist and the fingers: they are distinguished into the metacarpal bone of the thumb, fore-finger, &c.

(From µETA, after, METACARPIUS. and uzgros, the wrist.) Metacarpium. That part of the hand which is between the

wrist and the fingers.

METACARPUS. A muscle of the carpus. See Adductor metacarpi minimi digiti manus.

METACERASMA. (From mera, after, and κεξαντυμι, to mix.) Cerasma. A mixture tempered with any additional substance.

METACHEIRIXIS. (From μεταχειείζω, to perform by the hand.) Surgery. manual operation.

(From μεταχωςεν, to METACHORESIS. digress.) The translation of a disease from one part to another.

METACINEMA. (From pera and sives,

METALS. 495

to remove.) Diseased pupil of the eye, or distortion of it.

Metaconnylus. (From μετα, after, and κονδυλος, a knuckle.) The last joint of a finger, or that which contains the nail.

METALLAGE. (From μεταλλατίω, to change.) A change in the state or treat-

ment of a disease.

METALLURGIA. (From μεταλλον, a metal, and ερρον, work, labour.) That part of cllymistry which concerns the operations of metals.

METALS. We are at present acquainted with twenty-two metals, essentially dif-

fering from each other, namely,

Arsenic, Tungsten, Molybdena, Chrome, Columbium, Titanium, Uranium, Cobalt, Nickel, Manganese, Bismuth, Antimony, Tellurium, Mercury, Zinc, Tin, Lead, Iron, Copper, Silver, Gold, Platina,

The ancient division of these substances into noble or perfect, and semi or imperfect metals, is now abandoned, and we class them into different genera; proceeding in a gradation from those which possess, in a centain sense, the *least*, to those which possess the *most* metallic properties.

Classification of Metals.

1. Very brittle and acidifiable Metals.— Arsenic. Tungsten. Molybdena. Chrome. Columbium.

2. Less brittle and simply oxydable Metals.—Titanium. Uranium. Cobalt. Nickel. Manganese. Bismuth. Antimony. Tellurium.

3. Partly ductile and oxydable Metals.—

Mercury. Zinc.

4. Very ductile and ensily oxydable Metals.—Tin. Lead. Iron. Copper.

5. Exceedingly ductile and difficultly oxydable Metals.—Silver. Gold. Platina.

All the metals are found in the bowels of the earth, though sometimes they are on the surface. They are met with in different combinations with other matters, such as sulphur, oxygen, and acids; particularly with the carbonic, muriatic, sulphuric, and phosphoric acids. They are also found combined with each other, and sometimes, though rarely, in a pure metallic state, distinguishable by the naked eye.

In their different states of combination, they are said to be mineralized, and are The ores of metals are, called ORES. for the most part, found in nature in mountainous districts; and always in such as form a continued chain. There are mountains which consist entirely of iron ore, but, in general, the metallic part of a mountain bears a very inconsiderable proportion to its bulk. Ores are also met with in the cavities or crevices of rocks, forming what are termed VEINS, which are more easily discovered in these situations than when they lie level in plains.

The metallic matter of ores is very generally incrusted, and intermindled with some

earthy substance, different from the rock in which the vein is situated; which is termed its MATRIX. This, however, must not be confounded with the mineralizing substance with which the metal is combined, such as sulphur, &c.

General physical Properties of Metals.

All metals are combustible bodies. They possess a certain brilliancy, in consequence of the complete reflection of the light that falls upon them, which is termed metallic lustre. They are the most dense and heavy substances in nature; the heaviest fossil, not metallic, having a specific gravity much below that of the lightest metal. They are the most opaque of all bodies. A stone of the greatest opacity, when divided into thin plates, has more or less transparency; whereas gold is the only metal which admits of being reduced to such a degree of thinness as to admit the smallest perceptible transmission of light. Gold leaf, which is about 1-280,000 part of an inch in thickness, transmits light of a lively green colour; but silver, copper, and all the rest of the metals, are perfectly opaque. Another property, which belongs exclusively to metals, (though they do not all possess it,) is malleability; by which is meant a capacity of having their surface increased, either in length or breadth, without being liable to fracture. capacity is not precisely the same in those metals which do possess it, for some, which admit of extension when struck with a hammer, cannot be drawn into wire, which property is termed ductility: this property depends, in some measure, on another peculiar quality of metals, namely tenacity; by which is meant the power which a metallic wire, of a given diameter, has of resisting the action of a weight suspended from its extremity. All metals are fusible, though the degree of temperature at which this can be effected differs very much. Mercury is always fluid at the ordinary temperature of our atmosphere, while platina can scarcely be melted by the most intense heat of our furnaces. Metals are perfectly opaque when in a state of fusion; and are crystallizable when suffered to cool slowly and undisturbed. The tetrahedron and the cube are their primitive figures, though they very often take the octahedral form. They can likewise be volatalized at very high temperatures. They are the best conductors of caloric and electricity. Their susceptibility of combination is very great: they unite with carbon, sulphur, and phosphorus. They do not combine with earths by fusion; but their oxyds readily unite to acids, alkalies, and earths. They decompose water and several acids. Some effect this at common temperatures: some require a red heat, and others the interposition of another body. Water does not dissolve any of the metals, though it is a solvent of some of their oxyds. They are insoluble in ardent spirit, ether, or oils. They are all capable of combining with oxygen, though many of them require very high temperatures to effect this mnion, and others cannot be united to it but in an indirect manner. Most of the metals can be combined with each other; they then form alloys, many of which are of the greatest

utility in the arts. METAMORPHOPSIA. (From metamogφωσις, a change, and ofic, sight.) Visus defiguratus. Disfigured vision. It is a defect in vision, by which persons perceive objects changed in their figures. The species are, 1. Metamorphopsia acuta, when objects appear much larger than their size. 2. Metamorphopsia diminuta, when objects appear diminished in size, arising from the same causes as the former. 3. Metamorphopsia mutans, objects seem to be in motion; to the vertiginous and intoxicated persons, every thing seems to stagger. 4. Metamor-phopsia tortuosa seu flexuosa, when objects appear tortuous, or bending. 5. Metamorphopsia inversa, when all objects appear inverted. 6. Metamorphopsia imaginaria, is the vision of a thing not present, as may be observed in the delirious, and in maniacs. 7. Metamorphopsia from a remaining impression: it happens to those who very attentively examine objects, particularly in a great light, some time after to perceive the impression.

METAPEDIUM. (From μετα, after, and πες,

the foot ) The metatarsus.

METAPHRENUM. (From mera, after, and opens, the diaphragm.) That part of the back which is behind the diaphragm.

METAPOROPOIESIS. (From μετα, πορος, a duct, and ποιεω, to make.) A change in the

pores of the body.

METAPTOSIS (From μεταπιπτω, to digress) A change from one disease to another.

METASTASIS. (From μεθιστημι, to change, to translate.) The translation of a disease from one place to another.

METASYNCRISIS. (From μετασυγκεινω, to transmute.) Any change of constitu-

METATARSAL BONES. The five longitudinal bones between the tarsus and the toes; they are distinguished into the metatarsal hone of the great toe, fore

toe, &c.

METATARSUS. (From μετα, after, and ταgeos, the tarsus.) That part of the

foot between the tarsus and toes.

METELLA NUX. See Nux vomica.

METEORISMUS. (From μετεορος, a vapour.)

1. A flatulent dropsy.

2. A tympanitic state of the abdomen, taking place suddenly in acute diseases.

METEOROS. (Μετεωρος: from μεθα, and καιρα, to elevate.) Elevated, suspended, erect, sublime, tumid. Galen expounds pains of this sort, as being those which affect the periton xum, or other more su-

perficial parts of the body: these are opposed to the more deep-seated ones.

METHEGLIN. A drink prepared from honey by fermentation.

METHEMERINUS. (From µ672, and nµ692,

a day.) A quotidian fever.

METHODICA MEDICINA. Signifies that practice which was conducted by rules, such as are taught by Galen and his followers, in opposition to the empirical practice.

METHODUS. (From μετα, and οδος, a way.) The method, or ratio, by which any

operation or cure is conducted.

METOPION. Μετωτιεν. American sumach, a species of Rhus. It is a name of the bitter almond, also of an oil, or an ointment, made by Dioscorides, which was thus called because it had galbanum in it, which was collected from a plant called Metopium.

METOPIUM. Metamion. An ointment made

of galbanum.

METOPUM. (From μετα, after, and ωψ, the eye.) The forehead.

Metosis. A kind of amaurosis, from an excess of short sightedness.

METRA. (From untile, a mother.) The

METRENCHTTA. (From μετζα, the womb, and εγχυω, to pour into.) Injections into the

womb.

METRENCHYTES. (From μετζα, the womb, and εγχυα, to pour in.) A syringe to inject

fluids into the womb.)

METRITIS. (From μητζα, the womb.)
Inflammation of the uterus. See Hysteri-

tio

METROCELIDES. (From μητης, a mother, and μηλίς, a spot, or mole.) A mole, or mark, impressed upon the child by the mother's imagination.

METROCELIS. (From untrig, a mother, and under, a blemish.) A mole, or mark, impressed upon the child by the mother's

imagination.

METRO-MANIA. A rage for reciting verses. In the Acta Societatis Medicæ Havniensis, published 1779, is an account of a tertian attended with remarkable symptoms; one of which was the metro-mania, which the patient spoke extempore, having never before had the least taste for poetry; when the fit was off, the patient became stupid, and remained so till the return of the paroxysm, when the poetical powers returned again.

METROPTOSIS. (From μπτζα, the uterus, and πιπλω, to fall down.) Prolapsus uteri. The descent of the uterus

through the vagina.

METRORRHAGIA. (From μπτς2, the womb, and ξηγνυμι, το break out.) An excessive discharge from the womb.

MEU. See Meum athamanticum.

MEUM ATHAMANTICUM. (From µuων, less; so called, according to Minshew, from its diminutive size.) Meu. Spignel.

Baldmoney. The root of this plant, Æthusa mæum, is recommended as a carminative, stomachic, and for attenuating viscid humours, and appears to be nearly of the same nature as lovage, differing in its smell being rather more agreeable, somewhat like that of parsnips, but stronger, and being in its taste less sweet, and more warm, or acrid.

MEXICANUM. (From Mexico, whence it is brought.) A name of the balsam of

Peru.

Mexico seed. See Ricinus.

Mexico tea. See Botrys m. Mezereon. See Mezereum. See Botrys mexicana.

MEZEREUM. (A word of some barba-rous dialect.) Mezereon. Spurge-olive. Widow-wail. This plant, Daphne mezereum of Linnxus:-foribus sessilibus ternis caulinis, foliis lanceolatis deciduis, is extremely acrid, especially when fresh, and, if retained in the mouth, excites great and long continued heat and inflammation, particularly of the mouth and fauces; the berries also have the same effects, and, when is the part employed medicinally in the decoctum sarsaparille compositum, to assist mercury in resolving nodes and other obstinate symptoms of syphilis. The antisy-philitic virtues of mezereum, however, have been by many writers very justly doubted. The result of my own experience (says Mr. Pearson, of the Lock Hospital) by no means accords with the rcpresentation given of this root by former writers. From all that I have been able to collect, in the course of many years observation, I feel myself authorised to assert, unequivocally, that the mezereum has not the power of curing the venereal disease in any one stage, or under any one form. If a decoction of this root should ever reduce a venereal node, where no mercury has been previously given, yet the patient will by no means be exempted from the necessity of employing mercury for as long a space of time, and in as large a quantity, as if no mezereum had been taken. With respect to the power it is said to possess, of alleviating the pain, and diminishing the bulk of membranous nodes, nothing peculiar and appropriate can be ascribed to the mezereum on these accounts, since we obtain the same good effects from sarsaparilla, guaiacum, volatile alkali, blistering plasters, &c. Nevertheless, venereal nodes, which have subsided under the use of any of these articles of the materia medica, will appear again, and often with additional symptoms, if a full and efficacious course of mercury be not submitted to. It has, indeed, been al-leged, that mezereum always alleviates the pain occasioned by a venereal node, and generally reduces it, where the periosteum only is affected; and that it sel-

dom fails of removing those enlargements of the periosteum which have not yielded during the administration of mercury.

That some instances of success, in cases like these, may have fallen to the share of those who made the assertion, it would not become me to deny; but I have met with few such agreeable evidences of the efficacy of this medicine. I have given the mezereum in the form of a simple decoction, and also as an ingredient in compound decoctions of the woods, in many cases, where no mercury had been previously employed, but never with advantage to a single patient. I have also tried it, in numerous instances, after the completion of a course of mercury; yet, with the excep-tion of two cases, where the thickened state of the periosteum was removed during the exhibition of it, I never saw the least benefit derived from taking this medicine. In a few cases of anomalous pains, which I supposed were derived from irregularities during a mercurial course, the mezeswallowed, prove a powerful corrosive reum was of service, after I had tried the poison, not only to man, but to dogs, common decoction of the woods without wolves, and foxes. The bark of the root success; but even in this description of cases, I have always found it a very uncertain remedy. I have made trial of this vegetable in a great number of scrofulous cases, where the membranes covering the bones were in a diseased state, and I am not sure that one single patient obtained any evident and material benefit from

The late Dr. Cullen, whose reports may justly claim attention from all medical men, when treating of the mezereum, in his Materia Medica, says, "I have fre-quently employed it in several cutaneous affections, and sometimes with success." It were to have been wished, that the professor of medicine had specified what those diseases of the skin were, in which the mezereum was sometimes employed with success; for, if I except an instance or two of lepra, in which the decoction of this plant conferred a temporary benefit, I have very seldom found it possessed of medicinal virtue, either in syphilis, or in the sequelæ of that disease, in scrofula, or in cutaneous affections. Indeed the mezereum is of so acrimonious a nature, often producing heat and other disagreeable sensations in the fauces, and, on many occasions, disordering the primæ viæ, that I do not often subject my patients to the certain inconveniences which are connected with the primary effects of this medicine, as they are rarely compensated by any other important and useful qualities.

MEZEREUM ACETATUM. Very thin slices of the bark of the fresh mezereon root are to be steeped for twenty-four hours in common vinegar-The late Dr. Morris usually directed the application of this remedy to issues, when a discharge from them could not be encouraged by the

3 S \*

common means. It generally answers this purpose very effectually in the course of one night, the pea being removed, and a small portion of the bark applied over the opening.

MIASMA. (From μιανεω, to infect.) See

Contagion.

MICROCOSMIC BEZOAR. See Calculus.

MICROLEUCONYMPHÆA. (From mixeos, small, revues, white, and vougara, the waterlily.) The small white water fily.

MICRONYMPHEA. (From pingos, small, and νυμφαια, the water-lily.) The smaller

water-lily.

Microrchis. (From ungos, small, and oexis, a testicle.) One whose testicles are unusually small.

MICROSPHYXIA. (From pungos, small, and σφυξις, the pulse.) A debility and smallness

of the pulse.

Midriff. See Diaphragm.
Migma. (From μηνυω, to mix.) A con-

fection, or ointment.

MIGRANA. A corruption of hæmicrania. Milfoil, common. See Millefolium.

MILIARIA. (From milium, millet; so called because the small pustules, or vesicles, upon the skin resemble millet-seed.) Miliary fever. A genus of disease in the class pyrexia, and order exanthemata of Culien; characterized by synochus; cold stage considerable; hot stage attended with anxiety and frequent sighing; perspiration of a strong and peculiar smell; eruption, preceded by a sense of pricking, first on the neck and breast, of small red pimples, which in two days become white pustules, desquamate, and are succeeded by fresh pimples. Miliary fever has been observed to affect both sexes, and persons of all ages and constitutions; but females of a delicate habit are most liable to it, particularly in child-bed. Moist variable weather is most favourable to its appearance, and it occurs most usually in the spring and autumn. It is by some said to be a contagious disease, and has been known to prevail epidemically.

Very violent symptoms, such as coma, delirium, and convulsion-fits, now and then attend miliary fever, in which case it is apt to prove fatal. A numerous eruption indicates more danger than a scanty one. The eruption being steady is to be considered as more favourable than its frequently disappearing and coming out again, and it is more favourable when the places covered with the eruption appear swelled and stretched than when they remain flaccid. According to the severity of the symptoms, and depression of spirits, is the danger greater. See also Sudamina.

MILIOLUM. (Dim. of milium, millet.) A small tumour on the eyelids, resembling in

size a millet-seed.

MILITARIS. (From miles, a soldier; so called from its efficacy in curing fresh wounds.) See Millefolium.

MILITARIS HERBA. See Millefolium.

MILIUM. (From milium, a millet-seed.) Grutum. A very white and hard tubercle, in size and colour resembling a millet-seed. Its seat is immediately under the cuticle, so that, when pressed, the contents escape, appearing of an atheromatous nature.

MILIUM SOLIS. See Lithospermum.

Lac. A fluid secreted by MILK. peculiar glands, and designed to nourish young animals in the early part of their life. It is of an opaque white colour, a mild saccharine taste, and a slightly aromatic smell. It is separated immediately from the blood, in the breasts or udders of female animals. Man, quadrupeds, and cetaceous animals, are the only creatures which afford milk. All other animals are destitute of the organs which secrete this fluid. Milk differs greatly in the several animals.

The following are the Properties of ani-

mal and human milk:

Milk separates spontaneously into cream, cheese, and serum of milk; and that sooner in a warm situation than in a cold one. In a greater temperature than that of the air, it acesces and coagulates, but more easily and quicker by the addition of acid salts, or coagulating plants. Lime-water coagulates milk imperfectly. It is not coagulated by alkali pure, for it dissolves its caseous part. With carbonated alkali the caseous and cremoraceous parts of milk are changed into a liquid soap, which separates in the form of white flakes: such milk, by boiling, is changed into a yellow and then into a brown colour. Milk, distilled to dryness, gives out an insipid water, and leaves a whitish brown extract, called the extract of milk; which, dissolved in water, makes a milk of less value. Milk, fresh drawn, and often agitated in a warm place, by degrees goes into the vinous fermentation, so that alkohol may be drawn over by distillation, which is called spirit of milk. It succeeds quicker, if yeast be added to the milk. Mare's milk, as it contains the greatest quantity of the sugar of milk, is best calculated for vinous fermentation.

The Principles of milk, or its integral parts, are, 1. The Aroma, or odorous volatile principle, which flies off from freshdrawn milk in the form of visible vapour. 2. Water, which constitutes the greatest part of milk. From one pound, eleven ounces of water may be extracted by distillation. This water, with the sugar of milk, forms the serum of the milk. Bland oil, which, from its lightness, swims. on the surface of milk after standing, and forms the cream of milk. 4. Cheese, separated by coagulating milk, falls to the bottom of the vessel, and is the animal gluten. 5. Sugar, obtained from the serum of milk by evaporation. unites the caseous and butyraceous part with the water of the milk. 6. Some neu.

tral salts, as the muriate of potash and murinte of lime, which are accidental, not being found at all times, nor in every milk. These principles of milk differ widely in respect to quantity and quality, according

to the diversity of the animals.

The aroma of the milk is of so different an odour, that persons accustomed to the smell, and those whose olfactory nerves are very sensible, can easily distinguish whether milk be that of the cow, goat, mare, ass, or human. The same may be said of the serum of the milk, which is properly the seat of the aroma. The serum of milk is thicker and more copious in the milk of the sheep and goat, than in that of the ass, mare, or human milk. The butter of goats and cows is easily separated from the milk, and will not again unite itself with the butter-milk. Sheep's butter is soft, and not of the consistence of that obtained from the cow and goat. Asses', mares', and human butter, can only be separated in the form of cream; which cream, by the assistance of heat, is with ease again united to the milk from which it is separated. The cheese of cows' and goats' milk is solid and elastic, that from asses and mares soft, and that from slieep's milk almost as soft as gluten. It is never separated spontaneously from the milk of a woman, but only by art, and is wholly fluid. The serum abounds most in human, asses', and mares' milk. The milk of the cow and goat contains less, and that of the sheep least of all. The sugar of milk is in the greatest quantity in the mares and asses, and somewhat less in the human milk.

MILK, ASSES'. Asses' milk has a very strong resemblance to human milk in colour, smell, and consistence. When left at rest for a sufficient time, a cream forms upon its surface, but by no means in such abundance as a woman's milk. Asses' milk differs from cows' milk, in its cream being less abundant and more insipid; in its containing less curd; and in its possessing a

greater proportion of sugar.
MILK, COWS'. The milk of women, mares, and asses, nearly agree in their qualities; that of cows, goats, and sleep, possess properties rather different. Of these, cows' milk approaches nearest to that yielded by the female breast, but differs very much in respect to the aroma; it contains a larger proportion of cream and cheese, and less serum than human milk; also less sugar than mares' and asses' milk.

Cows' milk forms a very essential part of human sustenance, being adapted to every state and age of the body; but particularly

to infants, after being weaned.

MILK, EWES'. This resembles almost precisely that of the cow; its cream, however, is more abundant, and yields a butter not so consistent as cow's milk butter. makes excellent cheese.

MILK, GOATS'. It resembles cows', except in its greater consistence; like that milk, it throws up abundance of cream, from which butter is easily obtained.

MILK, HUMAN. The white, sweet-ish fluid, secreted by the glandular fabric of the breasts of women. The secretory organ is constituted by the great congrome-rate glands, situated in the fat or both breasts, above the musculus pectoralis ma-From each actius composing a mammary gland, there arises a radicle of a luctiferous or galactiferous duct. All these canals, gradually converging, are terminated without anastomosis, in the papillæ of the breasts, by many orifices, which, upon pressure, pour forth milk. The smell of fresh-drawn milk is peculiar, animal, fatuous, and not disagreeable. Its taste sweetish, soft, bland, agreeable. The spe-cific gravity is greater than water, but lighter than blood; hence it swims on it. Its colour is white and opake. In consistence it is oily and aqueous. A drop put on the nail flows slowly down, if the milk be

Time of Secretion. The milk most frequently begins to be secreted in the last mouths of pregnancy; but, on the third day after delivery, a serous milk, called Colostrum, is separated; and at length pure milk is secreted very copiously into the breasts, that, from its abundance, often spontaneously drops from the nipples.

If the secretion of milk be daily pro-moted by suckling an infant, it often continues many years, unless a fresh pregnancy supervene. The quantity usually secreted within twenty-four hours, by nurses, is various, according as the nourishment may be more or less chylous. It appears that not more than two pounds of milk are obtained from five or six pounds of meat. But there have been known nurses, who have given from their breasts two, or even more than three pounds, in addition to that which their child has sucked. That the origin of the milk is derived from chyle carried with the blood of the mammary arteries into the glandular facric of the breasts is evident, from its more copious secretion a little after meals; its dimmished secretion from fasting; from the smell and taste of food or medicines in the secreted milk; and lastly, from it spontaneous acescence; for humours perfectly animal become putrid.

The milk of a woman differs: 1. in respect to food. The milk of a woman who suckles, living upon vegeto-animal food, never acesces nor coagulates spontaneously, although exposed for many weeks to the heat of a furnace. But it evaporates gradually in an open vessel, and the last drop continues thin, sweet, and bland. The reason appears to be, that the caseous and cremoraceous parts cohere together, by means of the sugar, more intimately

than in the milk of animals, and do not so prevented. It does acesce, if mixed or boiled with vinegar, juice of lemons, cremor tartar, dilute sulphuric acid, or with the human stomach. It is coagulated with the acid of salt, or nitre, and by an acid gastric juice of the infant; for infants often vomit up the coagulated milk of the nurse. The milk of a sucking woman, who lives upon vegetable food only, like cows' milk, easily and of its own accord acesces, and is acted upon by all coagulating substances like the milk of animals. 2. In respect of the time of digestion. During the first hours of digestion the chyle is crude, and the milk less subacted; but towards the twelfth hour after eating, the chyle is changed into blood, and then the milk becomes yellowish and nauseous, and is spit out by the infant. Hence the best time for giving suck is about the fourth or fifth hour after meals. 3. In respect of the time after delivery. The milk secreted immediately after delivery is serous, purges the bowels of the infant, and is called colostrum. But in the following days it becomes thicker and more pure, and the longer a nurse suckles, the thicker the milk is secreted; thus, new-born infants cannot retain the milk of a nurse who has given suck for a twelve-month, on account of its spissitude. 4. In respect of food and medicines. Thus, if a nurse eat garlic, the milk becomes highly impregnated with its odour, and is disagreeable. If she in-dulge too freely in the use of wine or beer, the infant becomes ill. From giving a purging medicine to a nurse, the child also is purged; and, lastly, children affected with tormina of the bowels, arising from acids, are often cured by giving the nurse animal food, 5. In respect of the affections of the mind. There are frequent examples of rinfants being seized with convulsions from sucking mothers irritated by anger. infant of one year old, while he sucked milk from his enraged mother, on a sudden was seized with a fatal hæmorrhage, and died. Infants at the breast in a short time pine away, if the nurse be afflicted with grievous care; and there are also infants who, after every coition of the mother, or even if she menstruate, are taken ill.

The use of the mother's milk is, 1. It affords the native allinent to the new-born infant, in which respect milk differs little from chyle. Those children are the stronggest, who are nourished the longest by the mothers's milk. 2. The colostrum should not be rejected; for it relaxes the bowels, which in new-born infants ought to be open, to clear their intestines of the meconium. 3. Lactation defends the mother from a dangerous reflux of the milk into the blood, whence lacteal metastasis, and leucorrhæa, are so frequent in lying in women, who do not give suck. The mo-

tion of the milk also being hastened through the breast by the sucking of the child, prevents the very common induration of the breast, which arises in consequence of the milk being stagnated. 4. Men may live upon milk, unless they have been accustomed to the drinking of wine. For all nations, the Japanese alone excepted, use milk, and many live upon it alone.

MILK, MARES'. This is thinner than that of the cow, but scarcely so thin as human milk. Its cream cannot be converted into butter by agitation. The whey con-

tains sugar.

MILK BLOTCHES. An eruption of white vesicles, which assume a dark colour, resembling the blackening of the small-pox, and are succeeded by scabs producing an ichory matter, attended with considerable itchiness. It generally appears on the forehead and scalp, extending half over the face, and at times even proceeding farther. The period of its attack is the time of teething; and it is probably the same disease as the crustea lectea.

Milk fevor. See Puerperal fever.

Milk-teeth. See Teeth.

MILK-THISTLE. The leaves of this plant, when young, surpasses, when boiled, the finest cabbage, and possesses diuretic qualities. See also *Carduus mariæ*.

Milk-vetch. See Tragacantha. Milk-wort. See Polygala.

Milk-wort, rattle-snake root. See Seneka. MILLEFOLIUM. (From mille, a thousand, and folium, a leaf; named from its numerous leaves.) Achilea Myriophyllon. Chiliophullon. Lumbus veneris. Militaris herba. Stratiotes. Carpentaria. Speculum veneris. Common yarrow, or milfoil. The leaves and flowers of this indigenous plant, Achillea millefolium of Linnæus:—foliis bipianatis nudis; laciniis linearibus dentatis; caulibus superne sulcatis, have an agreeable, weak, aromatic smell, and a bitterish, rough, and somewhat pungent taste. They are both directed for medicinal use, in the Edinburgh Pharmacopæia; in the present practice, however, they are almost wholly neglected.

MILLEMORBIA. (From mille, a thousand, and morbus, a disease; so called from its use in many diseases.) See Scrophularia vulgaris.

MILLEPEDÆ. See Millepedes.

MILLEPEDES. (From mille, a thousand, and pes, a foot, named from their numerous feet.) Millipede. Wood-lice. The Oniscus asellus of Linneus. These insects, though they obtain a place in the pharmacopæias, are very seldom used medicinally in this country; they appear to act as stimulants and slight diuretics, and for this purpose they ought to be administered in a much greater dose than is usually prescribed. The expressed juice, or forty or fifty living millepedes, given in a mild

drink, is said to cure very obstinate jaundiccs.

MILLET-SEED. The fruit of the Panicum miliaceum of Linnaus. They are esteemed as a nutricious article of diet, and are often made into puddings in this country.

MILLET-SEED, INDIAN. The fruit of the Panicum italicum of Linnaus. It is much esteemed in Italy, being a constant ingredient in soups, and made into a variety of forms for the table.

MILLIUM. (From mille, a thousand; so called from the multitude of its seed.) Milium. The millet.

Mill-mountain. · See Linum Catharticum. MILPHOSIS. Μιλφωσις. A baldness of

the eyebrows.

MILTOS. MINTOS. Minium, or red-lead.

Miltwaste. See Geterach.

(From milza, the spleen, MILZADELLA. Span.; so called from its supposed virtues in diseases of the spleen.) The herb arch-

MIMOSA CATECHU. The systematic name of the tree which affords the terra japonica.

See Catechu.

MIMOSA NILOTICA. Supposed to be the tree which afforded the gum-arabic, but now considered to be the acacia vera. See Arabic gum.

MIMOSA SENEGAL. The systematic name of the tree from which the gum senegal

exudes.

Mindererus spirit. See Liquor ammoniæ acetatis.

MINERALIA. See Minerals.

MINERALOGY. That part of natural history which relates to minerals.

Mineral poisons. See Poisons.

MINERAL WATERS. .1qua mineralea, Aqua medicinales. Waters holding minerals in solution are called mineral waters. But as all water, in a mineral state, is impregnated, either more or less, with some mineral substances, the name mineral waters should be confined to such waters as are sufficiently impregnated with mineral matters to produce some sensible effects on the animal economy, and either to cure or prevent some of the diseases to which the human body is liable. On this account, these waters might be with much more propriety, be called medicinal waters, were not the name by which they are commonly known too firmly established by

The mineral waters which are the most esteemed, and consequently the most resorted to for the cure of diseases, are those

1. Aix. 2. Berege. 5. Buxton.

S. Bath. 4. Bristol. 6. Borset. 7. Cheltenham.8. Carlsbad.

17. Scarborough. 9. Epsom.

10. Harrowgate. 18. Spa. 11. Hartfell. 19. Sedlitz. 12. Holywell. 20. Sea-water.

13. Malvern. 21. Seltzer. 14. Matlock. 22. Tunbridge. 15. Moffat. 23. Vichy, and others 16. Pyrmont. of less note.

For the properties and virtues of these consult their respective heads.

Fourcroy divides all mineral and medicinal waters into nine orders, viz.

Cold alcidulous waters.

2. Hot or thernal acidulous waters.

3. Sulphuric saline waters. 4. Muriatic salinc waters.

5. Simple sulphureous waters.

6. Sulphurated gazeous waters. 7. Simple ferruginous waters.

8. Ferruginous and acidulous waters.

Sulphuric ferruginous waters.

Dr. Saunders arranges mineral waters into the following classes:

1. Simple cold.

thernal.

3. \_\_\_\_saline.

4. Highly carbonated alkaline.

5. Simple carbonated chalybeate. 6. Hot carbonated chalybeate.

7. Highly carbonated chalybeate. 8. Saline carbonated chalybcate.

9. Hot saline highly carbonated chalvbeate.

10. Vitriolated chalybeate.

11. Cold, sulphureous. 12. Hot, alkaline, sulphureous.

In order to present the reader, under one point of view, with the most conspicuous features in the composition of the mineral waters of this and some other countries, the following Synoptical Table is subjoined, from Dr. Saunders' works on mineral waters.

The reader will please to observe, that under the head of Neutral Purging Salts are included the sulphats of soda and magnesia, and the muriats of lime, soda, and magnesia. The power which the earthy muriats may possess of acting on the intes-tinal canal is not quite ascertained, but, from their great solubility, and from analogy with salts, with similar component parts, we may conclude that this forms a principal part of their operation.

The reader will likewise observe, that where the spaces are left blank, it signifies that we are ignorant whether any of the substance at the head of the column is contained in the water; that the word none implies a certainty of the absence of that substance; and the term uncertain means that the substance is contained, but,

that the quantity is not known.

Mr. Henry, in his epitome of chymistry, gives the following concise and accurate account for the analysis of mineral wa-

Water is never presented by nature in a state of complete purity. Even when collected as it descends in the form of rain, chymical tests detect in it foreign ingredients. And when it has been absorbed by the earth, has traversed its different strata, and is returned to us by springs, it is found to have acquired various impregnations. The readiest method of judging of the contents of natural waters is by applying what are termed tests, or reagents, i. e. substances which, on being added to a water, exhibits, by the phoenomena they produce, the nature of the saline and other ingredients. For example, if, on adding an infusion of litmus to any water, its colour is changed to red, we infer that the water contains an uncombined acid; if this change ensue even after the water has been boiled, we judge that the acid is a fixed and not a volatile one: and if, on adding the muriate of barytes, a precipitate falls down, we safely conclude that the peculiar acid present in the water is either entirely or in part the sulphuric acid. Mr. Henry first enumerates the tests generally employed in examining mineral waters, and describes their ap-plication, and afterwards indicates by what particular tests the substances generally found in waters may be detected.

A. Infusion of Litmus. Syrup of Violets, &c - As the infusion of litmus is apt to spoil by keeping, some solid litmus should The infusion is prepared by be kept. steeping this substance, first bruised in a mortar, and tied up in a thin rag, in distilled water, which extracts its blue co-If the colour of the infusion tends too much to purple, it may be amended by a drop or two of pure aminonia; but of but not by carbonated earths. this no more should be added that what is 3. The red infusion of Bra barely sufficient, least the delicacy of the test should be impaired. The syrup of violets is not easily obtained pure. The genuine syrup may be distinguished from the spurious by a solution of corrosive sublimate, which changes the former to green, while it reddens the latter. When it can be procured genuine, it is an excellent test of acids, and may be employed in the same manner as the infusion of litmus. Paper stained with the juice of the marsh violet, or with that of radishes, answers a similar purpose. In staining paper for the purpose of a test, it must be used unsized; or, if sized, it must previously be washed with warm water; because the alum which enters into the composition of the size will otherwise change the vegetable colour to a red.

Infusion of litmus is a test of most uncombined acids.

If the infusion redden the unboiled but not the boiled water under examination, or if the red colour occasioned by adding the infusion to a recent water return to blue on boiling, we may infer that the acid is a volatile one, and most probably the carbonic acid. Sulphuretted hydrogen gas, dissolved in water, also reddens litmus, but not after boiling. To ascertain whether the change be produced by carbonic acid, or sulphuretted hydrogen, when experiment shews that the reddening cause is volatile, add a little lime-water. This, if carbonic acid be present, will occasion a precipitate, which will dissolve with effervescence, on adding a little muriatic acid. Sulphuretted hydrogen may also be contained in the same water, which will be ascertained by the tests hereafter to be described.

Paper tinged with litmus is also reddened by the presence of carbonic acid, but regains its blue colour by drying. The mineral and fixed acids redden it permanent-That these acids, however, may produce their effect, it is necessary that they should be present in a sufficient propor-

Infusion of litmus reddened by vinegar-Spirituous tincture of Brazil wood-Tincture of turmeric, and paper stained with each of these three substances-Syrup of violets. All these different tests have one and the same object.

1. Infusion of litmus reddened by vinegar, or litmus paper reddened by vinegar, has its blue colour restored by alkalis and pure earths, and by carbonated alkalis and earths.

2. Turmeric paper and tincture are changed to a reddish brown by alkalis, whether pure or carbonated, and by pure earths;

3. The red infusion of Brazil wood, and paper stained with it, become blue by alkalis and earths, and even by the latter, when dissolved by an excess of carbonic acid. In the last mentioned case, however, the change will either cease to appear, or be much less remarkable, when the water has been boiled.

4. Syrup of violets, when pure, is by the same causes turned green, as also paper stained with the juices of violets, or raddishes.

B. Tincture of Galls.

Tincture of galls is the test generally employed for discovering iron, with all the combinations of which it produces a black tinge, more or less intense, according to the quantity of iron. The iron, however, in order to be detected by this test, must be in the state of red oxyd, or, if oxydated in

a less degree, its effects will not be apparent, unless after standing some time in contact with air. By applying this test before and after evaporation, or boiling, we may know whether the iron be held in solution by carbonic acid or a fixed acid; for,

1. If it produce its effects before the application of heat, and not afterwards, car-

bonic acid is the solvent.

2. If after, as well as before, a mineral

acid is the solvent.

3. If, by the boiling, a yellowish powder be precipitated, and yet galls continue to strike the water black afterwards, the iron, as often happens, is dissolved both by carbonic acid and a fixed acid. A neat mode of applying the gall test was used by M. Klaproth, in his analysis of the Carlsbad water. A slice of the gall-nut was suspended by a silken thread, in a large bottle of the recent water; and so small was the quantity of iron, that it could only be discovered in water fresh from the spring.

C. Sulphuric Acid.

1. Sulphuric acid discovers, by a slight effervescence, the presence of carbonic acid, whether uncombined or united with alkalis, or earths.

2. If lime be present, whether pure or uncombined, the addition of sulphuric acid occasions, after a few days, a white pre-

· cipitate.

3. Barytes is precipitated instantly in the

form of a white powder.

4. Nitrous and muriatic salts, on adding sulphuric acid and applying heat, are decomposed; and if a stopper, moistened with pure ammonia, be held over the vessel, white clouds appear. For distinguishing whether nitric or muriatic acid be present, rules will be given hereafter.

Nitric and Nitrous Acids.

These acids, if they occasion effervescence, give the same indications as the sulphuric. The nitrous acid has been recommended, as a test distinguishing between hepatic waters that contain sulphuret of potash, and those that only contain sulphuretted hydrogen gas. In the former case, a precipitate ensues on adding nitrous acid, and a very fortid smell arises; in the latter, a slight cloudiness only appears, and the smell of the water becomes less disagreeable.

D. Oxalic Acid and Oxalates.

This acid is a most delicate test of lime, which it separates from all its combina-

1. If a water, which is precipitated by oxalic acid, becomes milky on adding a watery solution of carbonic acid gas, or by blowing air through it by means of a quill, or glass tube, we may infer that pure lime

(or barytes, which has never yet been found pure in water) is present.

2. If the oxalic acid occasion a precipitate before, but not after boiling, the lime is dissolved by an excess of carbonic acid.

3. If, after boiling by a fixed acid, a considerable excess of any of the mineral acids, however, prevents the oxalic acid from occasioning a precipitate, even though lime be present; because some acids decompose the oxalic, and others, dissolving the oxalate of lime, prevent it from ap-

pearing. The oxalate of ammonia, or of potash, (which may easily be formed by saturating their respective carbonates with a solution of oxalic acid) are not liable to the above objections, and are preferable, as reagents, to the uncombined acids. Yet even these oxalates fail to detect lime when supersaturated with muriatic or nitric acids; and if such an excess be present, it must be saturated before adding the test with pure ammonia. Fluat of ammonia is the best test of lime. It is made by adding carbonate of ammonia to diluted fluoric acid.

E. Pure Alkalis and Carbonated Alkalis.

1. The pure fixed alkalis precipitate all earths and metals, whether dissolved by volatile or fixed menstrua, but only in certain states of dilution: for example, sulphate of alumine may be present in water, in the proportion of 4 grains to 500, without being discovered by pure fixed alkalis. As the alkalis precipitate so many substances, it is evident they cannot afford any precise information when employed as reagents. From the colour of the precipitate, as it approaches to pure white, or recedes from it, an experienced eye will judge that the precipitated earth contains less or more of the metallic admixture.

2. Pure fixed alkalis decompose all salts with basis of ammonia, which becomes evident by its smell, and also by the white fumes it exhibits when a stopper is brought near it, moistened with muriatic acid.

3. Carbonates of potash and soda have

similar effects.

4. Pure ammonia precipitates all earthy and metallic salts. Besides this property, it also imparts a deep blue colour to any liquid that contains copper in a state of solution.

Carbonate of ammonia has the same properties, except that it does not precipitate magnesia from its combinations. Hence, to ascertain whether this earth be present in any solution, add the carbonate of ammonia till no further precipitation ensues, filter the liquor, and then add pure ammonia. If any precipitation now occurs, we may infer the presence of magnesia.

Y. Lime-Water.

1. Lime-water is applied for the purposes of a test, chiefly for detecting carbonic acid. Let any liquor, supposed to contain this acid, be mixed with an equal bulk of this acid. If carbonic acid be present, either free or combined, a precipitate will immediately appear, which, on adding a few drops of muriatic acid, will immediately dissolve with effervescence.

2. Lime-water will immediately shew the presence of corrosive sublimate, by a brick-dust coloured sediment. If arsenie be present in any liquid, lime-water, when added, will occasion a precipitate, consisting of lime and arsenic, which is very difficultly soluble in water. This precipitate, when mixed up with oil, and laid on the hot coals, yields the well-known garlic smell of arsenic.

G. Pure Barytes, and its Solution in Water.

1. A solution of pure barytes is even more effectual than lime-water, in detecting the presence of carbonic acid, and is much more portable and convenient; since from the crystals of this earth, the solution may at any time be prepared. In discovering fixed air, the solution of barytes is used similarly to lime-water; and, if this acid be present, gives, in like manner, a precipitate soluble with effervescence in muriatic acid.

Pure strontites has similar virtues as a test.

11. Metals.

1. Of the metals, silver and mercury are tests of the presence of sulphurets, and of sulphuretted hydrogen gas. If a little quicksilver be put into a bottle, containing water impregnated with either of these substances, its surface soon acquires a black film, and, on shaking, a blackish powder separates from it. Silver is immediately tarnished from the same cause.

2. The metals also may be used as tests of each other, on the principle of elective affinity. Thus, for example, a polished iron plate, immersed in a solution of sulphate of copper, soon acquires a coat of this metal, and the ssme in other similar

examples.

I. Sulphate of Iron.

This is the only one of the sulphrices, except that of silver, applicable to the purposes of a test. When used in this view, it is generally employed to ascertain the presence of oxygenous gas, of which a natural water may contain a small quantity.

A water suspected to contain this gas, may be mixed with a little recently dissolved sulphate of iron, and kept corked up. If an oxyd of iron be precipitated in the course of a few days, the water may be inferred to contain oxygeneus gas.

Sulphate, Nitrate, and Acetate of Silver. These solutions are, in some measure,

applicable to the same purpose.

1. They are peculiarly adapted to the discovery of muriatic acid and muriates. For the silver, quitting the nitric acid, combines with the muriatic, and forms a flaky precipitate, which at first is white, but, on exposure to the sun's light, acquires a bluish colour. This precipitate, Dr. Black states to contain, in 1000 parts, as much muriatic acid as would form 425 parts and a half of chrystallised muriate of soda, which estimate scarcely differs at all from that of Klaproth. A precipitation, however, may arise from other causes, which it may be proper to state.

2. The solutions of silver in acids are precipitated by carbonated alkalis and earths. The agency of these may be prevented by previously adding a few drops of the same acid in which the silver is dis-

solved.

3. The nitrate and acetate of silver are decomposed by the sulphuric and sulphureous acids; but this may be prevented by adding previously a few drops of nitrate or acetite of barytes, and after allowing the precipitate to subside, the clear liquor may be decanted, and the solution of silver added. Should a precipitation now take place, the presence of muriatic acid, or some one of its combinatious, may be suspected. To obviate uncertainty, whether a precipitation be owing to sulphuric or muriatic acid, a solution of sulphure of silver may be employed, which is effected only by the latter acid.

4. The solutions of silver are precipitated by extractive matters; but in this case also the precipitate is discoloured, and is

soluble in nitrous acid.

K. Nitrate and Acetate of Lead.

1. Aceite of lead, the most eligible of these two tests, is precipitated by sulphuric and muriatic acids; but as, of both these, we have much better indicators, it is not necessary to enlarge on its application to

this purpose.

2. The acetite is also a test of sulphuretted hydrogen and of sulphurets of alkalis, which occasion a black precipitate; and if a paper on which characters are traced with a solution of acetite of lead, be held over a portion of water containing sulphuretted hydrogen, they are soon rendered visible.

3. The acetite of lead is employed in the discovery of uncombined boracic acid, a very rare ingredient of waters. To ascertain whether this be present, some cautions are necessary. The uncombined alkalis and earths (if any be suspected) must be saturated with acetic or acetous acid. The sulphates must be decomposed by acetite or narate of barytes, and the

muriates by acetite or nitrate of silver. The filtered liquor, if boracic acid be contained in it, will give a precipitate soluble in nitric acid of the specific gravity of 1.3.

L. Nitrate of Mercury prepared with and without Heat.

This solution, differently prepared, is sometimes employed as a test. But, since other tests answer the same purposes more effectually, it is not absolutely necessary to have these tests.

M. Muriate, Nitrate, and Acetite

of Barytes.

1. These solutions are all most delicate tests of sulphuric acid and of its combinations, with which they give a white precipitate, insoluble in dilute muriatic acid. They are decomposed, however, by carbonates of alkali; but the precipitate occasioned by these is soluble in dilute muriatic and nitric acid with effervescence, and may even be prevented by adding previously a few drops of the acid contained in the

barytic salt.

One lundred grains of dry sulphate of barytes (acording to Klaproth, p. 168.) contains about 45 one-fifth of sulphuric acid, of the specific gravity 1850, according to Clayfield, 33 of acid of s. g. 2240, according to Thenard, after calcination about 25. These estimates differ very considerably. From Klaproth's experiments it appears that 1000 grains of sulphate of barytes indicate 595 of desiccated sulphate of soda, or 1416 of the crystallized salt. The same chymist has shewn that 100 grains of sulphate of barytes are produced by the precipitation of 71 grains of sulphate of lime.

2. Phosphoric salts also occasion a precipitate which is soluble in muriatic acid

without effervescence.

N. Prussiates of Potash and Lime.

Of these two, the prussiat of potash is the most eligible. When pure, it does not speedily assume a blue colour on the addition of acid, nor does it immediately precipitate muriated barytes. Prussiat of potash is a very sensible test of iron, with the solutions of which in acids it produces a Prussian blue precipitate, in consequence of a double elective affinity. To render its effect more certain, however, it may be proper to add, previously to any water suspected to contain iron, a little muriatic acid, with a view to the saturation of uncombined alkalis, or earths, which, if present, prevent the detection of any minute portions of iron.

1. If a water, after boiling and filtration, does not afford a blue precipitate on the addition of prussiat of potash, the solvent of the iron may be inferred to be a volatile one, and probably the carbonic acid

2. Should the precipitation ensue in the boiled water, the solvent is a fixed acid,

the nature of which must be ascertained by other tests.

O. Solution of Soap in Alkohol.

This solution may be used to ascertain the comparative hardness of waters. With distilled water it may be mixed without producing any change; but, if added to a hard water, it produces a milkiness, more or less considerable as the water is less pure; and from the degree of milkiness as experienced eye will judge of its quality. The acids, alkalis, and all earthy and metallic salts, decompose soap, and occasion that property in water termed hardness.

Alkohol.

Alkohol, when mixed with any water in the proportion of about an equal bulk, precipitates all the salts which it is capable of dissolving.

P. Hydro-sulphuret of Ammonia.

This and other sulphurets, as well as water saturated with sulphurated hydrogen, may be employed in detecting lead and arsenic, with the former of which they give a black, and with the latter a yellowish precipitate. As lead and arsenic, however, are never found in natural waters, these tests are not required.

MINERALS. (Mineralia; from mina, a mine of metal.) All substances which do not possess organization, or are not produced by an organized body, belong to the class called minerals. Among this varied class of materials, which require the attention of the chymist and manufacturer, many are compounded of such principles and formed under such circumstances and situations in the earth, that it is difficult to distinguish them without having recourse to the test of experiment; several are formed with considerable regularity as to the proportion of their principles, their fracture, their colour, specific gravity, and figure of crystallization.

Mineral bodies which enter into the composition of the globe, are classed by mineralogists under four heads:—1. Earths. 2. Salts. 3. Inflammable fossils; and 4. Metals and their ores. Under the term earths are arranged stones and earths, which have no taste, and do not burn when

heated with contact of air.

Under the second, salts, or those saline substances which melt in water and do not burn, they require, according to Mr. Kirwan, less than two hundred times their weight of water to dissolve them.

By inflammable fossils are to be understood all those minerals not soluble in water, and exhibiting a flame more or less evident when exposed to fire in contact with air.

The fourth class, or ores, are compound bodies. Nature has bestowed their proper metallic appearance on some substances, and when this is the case, or they are alloyed with other metals, or semi-metals, they are called native metals. But such as are distinguished, as they commonly are, in mines, in combination with some other unmetallic substances, are said to be mineralized. The substance that sets them in that state, is called the mineralizer, and the compound of both, an ore. For example, in the common ore of copper, this metal is found oxydated, and the oxyd combined with sulphur. The copper may be considered as mineralized with oxygen and sulphur, and the compound of the three bodies forms an ore of copper.

Mineral salts. See Sults.

MINIMUM. A minim. The sixticth part of a drachm. An important change has been adopted in the last London Pharmacopæia, for the mensuration of liquids, and the division of the wine pint, to insure accuracy in the measurement of qualities of liquids below one drachm. The number of drops contained in one drachm has been assumed to be sixty; and taking water as a standard, this number, though by no means accurate, would still be sufficient for ordinary purposes; but when other liquids of less specific gravity are used, a much larger number is required to fill the same measure, as of proof spirit, 140 drops are required to equal the bulk of 60 of water, dropped from the same vessel. If, therefore, in the composion of medicines, measures suited to the standard of water were used occasionally only, and it was generally assumed that sixty drops were equal to one fluid-drachm, and one fluid-drachm was substituted for sixty drops prescribed, twice the dose intended would be given. There are further objections to the use of drops; that their bulk is influenced by the quantity of liquid contained, in the bottle from which they fall, by the thickness of the lip, and even by the inequalities on the surface of the lip of the same bottle; that volatile liquids, to which this mode is most commonly applied, are thus exposed with extensive surfaces, and their evaporation promoted, and on all these accounts the adoption of some decisive convenient and uniform substitute became necessary. The subdivision of the wine pint has therefore been extended to the sixtieth part of the fluid-drachm, which is termed minim; and glass measures, expressive of such subdivision have been adapted by the college.

MINIUM. Red lead. See Lead.
MINIUM GRECORUM. Native cinnabar.
Mint, common. See Mentha sativa.
Mint, pepper. See Mentha piperita.
Mint, water. See Mintha aquatica.
Miscarriage. See Abortion.
MISFERE MEI. (Have compassion on

me; so called from its unhappy torments.)
The liliac passion.

Mislaw. See Musa paradisiaca.

Misocurmicus. Thus some were called who professed themselves enemies to the chymists, and their enthusiastic conceits.

MISPICKLE. A white, brilliant, granulated iron ore, composed of iron in combi-

nation with arsenic.

Missletoe. See Viscum.
MISTURA, A mixture. A fluid composed of two or more ingredients. It is mostly contracted in prescriptions thus, mist, e. g.—f. mist. which means, let it be made into a mixture.

MISTURA CAMPHORE. Camphire mixture. "Take of camphor, half a drachm; rectified spirit, ten minims; water, a pint. First rub the camphor with the spirit, then with the water gradually added, and strain the liquor." A very elegant preparation of camphire, for delicate stomachs, and those who cannot bear it in substance, as an antispasmodic and nervine. There is a great loss of camphire in making it as directed by the pharmacopæia. Water can only take up a certain quantity. For its virtues, see Camphora.

MISTURA CORNU USTI. "Take of hartshorn, burnt and prepared, two ounces; acacia gum, an ounce; water, three pints." Boil down to two pints, constantly stirring, and strain. For its virtues, see Cornu.

MISTURA CRETE. Chalk mixture. "Take of prepared chalk, half an ounce; refined sugar, three drachms; gum arabic, powdered, half an ounce." Mix. A very useful and pleasant form of administering chalk as an adstringent and antacid. It is particularly calculated for children, in whom it allays the many deranged actions of the prime vize, which are produced by acidities. Dose, one ounce to three, frequently, See Creta and Carbonas calcis.

MISTURA FERRI COMPOSITA. " Take of myrrh, powdered, a drachm; subcarbonate of potash, twenty-five grains; rose-water, seven ounces and a half; sulphate of iron, powdered, a scruple; spirit of nutmeg, an ounce; refined sugar, a drachm. Rub together the myrrh, the subcarbonate of potash and sugar; and, during the trituration, add gradually, first, the rose water and spirit of nutmegs, and last, the suiphate of iron. Pour the mixture immediately into a proper glass bottle, and stop it close," This preparation is the celebrated mixture of Dr. Griffiths. A chymical decomposition is effected in forming this mixture, a subcarbonate of iron is formed, and a sulphate of potash.

MISTURA GUALACI. "Take of guaiacum gnm resin, a drachm and a halt; refined sugar, two drachms; mucilage of acacia gum, two fluid ounces; cinnamon water, eight fluid ounces. Rub the guniacum with the sugar, then with the mucilage; and, when they are mixed, pour on the cinnamon water gradually." For its virtues

see Guaiacum.

MISTURA MOSCHI. "Take of musk, acacia gum, powdered, refined sugar, of each a drachm; rose-water, six fluid ounces." Rub the musk first with the sugar, then with the gum, and add the rose-water by degrees. An excellent diaphoretic and antispasmodic. It is by far the best way of administering musk; when boluses cannot be swallowed. Dose, one ounce to three, frequently.

Mithridate mustard. See Thluspi cam-

pestre.

The electuary called MITHRIDATIUM. Mithridate, from Mithridates, king of Pontus and Bythinia, who experienced the virtues of the simples separately, afterwards combined them; but then the composition consisted of but few ingredients, viz. twenty leaves of rue, two walnuts, two figs, and a little salt: of this he took a dosc every morning, to guard himself against the effects of poison.

MITRAL VALVES. Valvule mithrales. The valves of the left ventricle of the heart are so called from their resemblance to a

mitre.

MIVA. An antient term for the form of a medicine, not unlike a thick syrup, now called Marmalade.

MIXTURE. 1. See Mistura.

2. Chymical mixture should be distinguished from the chymical solution; in the former, the aggregate particles can again be separated by mechanical means, and the proportion of the different particles determined; but, in solution, no mechanical power whatsoever can separate them.

Mochlia. (From μοχλος, a lever.) A reduction of the bones from an unnatural

to a natural situation.

Mochlics. (From μοχλευω, to move.) Violent purges.

MODIOLUS. (Dim. of modus, a measure.) The nucleus, as it were, of the cochlea of the ear is so termed. It ascends from the basis of the cochlea to the apex.

Mofette. See Nitrogen.

MOFFAT WATER. A cold snlphureous water, of a very simple composition. miles south-west of Edinburgh, affords this mineral water; when first drawn, it appears rather milky and bluish; the smell is exactly similar to that of Harrogate, the smell is sulphureous and saline, without any thing bitter. It sparkles somewhat on being poured from one glass to another.

According to Dr. Garnett's analysis, a wine gallon of Moffat water contains thirty-

six grains of muriate of soda, five cubic inches of carbonic acid gas, four of azotic gas, and ten of sulphurated hydrogen, making altogether nineteen cubic inches of gas. Moffat water is, therefore, very simple in its composition, and hence it produces effects somewhat similar to those of Harrogate. It is, perhaps, on this account also that it so soon loses the hepatic gas, on which depends the greater part of its medicinal power. The only sensible effect of this water is that of increasing the flow of urine; when it purges, it appears rather to take place from the expessive dose than from its mineral ingredients. This water appears to be useful chiefly in cutaneous eruptions, and as an external application in an increased temperature, scrofula in its early stage appears to be alleviated, it is also used as an external application to irritable ulcers, and is recommended in dyspepsia, and where there is inaction of the alimentary canal.

MOGILALIA. (From μονις, difficulty, and λαλιω, to speak. A difficulty of speech.

Mola. (Heb.) 1. The knee-pan; so named because it is shaped like a mill-stone. 2. A mole, or shapeless mass of flesh in the uterus. Sec Mule.

MOLAR GLANDS. Glandulæ molares. Two salival glands situated on each side of the mouth, between the masseter and buccinator muscles, the excretory ducts of which open near the last dens molaris.

(From molaris, a grind-MOLARIS. stone; because they grind the food.) A double-tooth. See Teeth.

Molasses. See Treacle.

Melissa Tursica, Turkey MOLDAVICA. balsam. Canary balsam. Balsam of Gilead. This plant, Dracocephalum moldavica; floribus verticellatis, bracteis lanceolatis, serraturis capillaleis of Linnxus, affords a fragrant essential oil, by distillation, known in Germany by the name of cleum syriae. The whole herb abounds with an aromatic smell, and an agreeable taste, joined with an aromatic flavour; it is recommended to give tone to the stomach and nervous system.

MOLE. Mola. By this term authors have intended to describe different productions of, or excretions from the uterus.

By some it has been used to signify every Moffat, a village situated about fifty-six kind of fleshy substance, particularly those which are properly called polypi; by others, those only which are the consequence of imperfect conception, or when the ovum is in a morbid or decayed state; and by many, which is the most popular opinion, every coagulum of blood which continues long enough in the uterus to assume in form, and to have only the fibrous part, as it has been called, remaining, is denominated a mole.

There is surely much impropriety, says Dr. Denman, in including, under one general name, appearances so contrary, and substances so different.

For an account of the first kind, see Po-

lyfnis.

Of the second kind, which has been defined as an own deforme, as it is the consequence of conception, it might more justly be arranged under the class of monsters; for though it has the appearance of a shapeless mass of flesh, if examined carefully with a knife, various parts of a child may be discovered, lying together in apparent confusion, but in actual regularity. The pedicle also by which it is connected to the uterns, is not of a fleshy texture, like that of the polypus, but has a regular series of vessels like the umbilical cord, and there is likewise a placenta and membranes containing water. The symptoms attending the formation, growth, and expulsion of this apparently confused mass from the uterus, corresponding with those of a wellformed child.

With respect to the third opinion of a mole, an incision into its substance will discover its true nature; for, although the external surface appears at the first view to be organized flesh, the internal part is composed merely of coagulated blood. As substances of this kind, which mostly occur after delivery, would always be expelled from the action of the uterus, there seems to be no reason for a particular inquiry, if popular opinion had not annexed the idea of mischief to them, and attributed their formation or continuance in the utcrus to the negligence or misconduct of the practitioner. Hence the persuasion arose of the necessity of extracting all the coagula of blood out of the uterus, immediately after the expulsion of the placenta, or of giving medicines to force them away; but abundant experience hath proved, that the retention of such coagula is not, under any circumstances, productive of danger, and that they are most safely expelled by the action of the uterns, though at very different periods after their formation.

MOLLE. Indian mastich.

MOLLITIES OSSIUM. (Mollities, from mollis, soft.) A disease of the bones, wherein they can be bent without fracturing them, in consequence either of the inordinate absorption of the phosphate of lime, from their natural solidity is derived, or else of this matter not heing duly secreted and deposited in their fabric. Is rickets, the bones only yield and become distorted by slow degrees, and retain their natural inflexibility; but in the present disease they may be at once bent in any direction. The mollities ossium is rare, and its causes not well understood. All the cases of mollities ossium yet on record have proved

fatal, and no means of cure are yet known. On dissection of those who have died, all the bones, except the teeth, have been found unusually soft, so that scarce any of them could resist the knife, the periosteum has been found thicker than usual, and the bones have been found to contain a great quantity of oily matter and little earth.

MOLLITIES UNGUINUM. A preternatural softness of the nails; it often accom-

panies chlorosis.

Mollificatio. A barbarous term of a palsy of the muscles in any particular part. Mollicense lienum. See Lignum pavuna.

MOLYBDAT. Molybdas. A salt formed by the union of the molybdic acid with different bases: thus, molybdat of alumin,

molybdat of antimony, E-c.

MOLYBDENA. (From monuffer, lead.) Molybditis. A metal which exists mineralized by sulphur in the ore called sulphuret of Molybdena. This ore, which is very scarce, is so similar in several of its properties to plumbago that they were long considered as varieties of the same substance. It is of a light lead-grey colour, its surface is smooth, and feels unctuous, its texture is lamellated, it soils the fingers, and marks paper bluish-black, or silver-grey. It may be cut with a knife. It is generally found in compact masses; seldom in particles, or crystalized. It is met with in Sweden's Spain, Saxony, Siberia, and Iceland. Scheele shewed that a peculiar metallic acid might be obtained from it; and later chymists have succeeded in reducing this acid to the metallie state. We are indebted to Mr. Hatchett, for a full and accurate analysis of

The native sulphuret of molybdena is the only ore hitherto known which contains this metal.

Properties of Molybdena - Molybdena is either in an agglutinated blackish friable mass, having little metallic brilliancy, or in a black powder. The mass slightly united, shews, by a magnifying glass, small round brilliant grains. Its weight is from 6 600 to 7.500. It is one of the most infusible of the metals. It is capable of combining with a number of metals by fusion. It forms with sulphur an artificial sulphuret of molybdena analogous to its ore. It unites also to phosphorous. The affinity of molybdena for oxygen is very feeble, according to Mr. Hatchett. The alkalies have no action on molybdena in the moist way, but it enters readily into fusion with potash and soda. It is oxydable by boiling sulphuric acid, and acidifiable by the nitric acid. Muriatic acid does not act upon it. It is capable of existing in not less than four different degrees of oxygenation.

Method of obtaining Molybdena. - To oh.

tain molybdena is a task of the utmost difficulty. Few chymists have succeeded in producing this metal, on account of its great infusibility. The method recommended in general is the following:—Molabdic acid is to be formed into a paste with oil, dried at the fire, and then exposed to a violent heat in a crucible lined with charcoal. By this means the oxyd becomes decomposed; a black agglutinated substance is obtained, very brittle under the finger, and having a metallic brilliancy. This is the metal called molybdena.

MOLYBDITIS. See Molybdena.

MOLYBDOS. (OTI MONEI ELS BABOS, from its

gravity.) Lead.

Molyza. (Dim. of μωλυ, moly.) Garlic, whose head, like moly, is not divided into

Momiscrs. (From μωμος, a blemish.) That part of the teeth which is next the gums, and which is usually covered with a foul tartareous crust.

MOMORDICA. The name of a genus of plants in the Linnzan system. Class,

Monoecia. Order, Syngenesia.

Momordica ellaterium. (Momordica; from mordeo, to bite; from its sharp taste.) The systematic name of the squirting cu-

cumber. See Elaterium.

MONARDA FISTULOSA. The systematic name of the purple monarda. The leaves of this plant have a fragrant smell, and an aromatic and somewhat bitter taste, possessing nervine, stomachic, and deobstruent virtues. An infusion is recommended in the cure of intermittent fevers.

MONELLI. A species of Anagallis.

Money-wort. See Nummularia.

Monks rhubarb. See Rhaburbarum monachorum.

oculus, the eye.) A name given cacum, or blind gut, by Paracelsus, because it is perforated only at one end.

Monoculus. (From mores, one, and oculus, an eye.) Monopia. A very uncommon species of monstrosity, in which there is but one eye, and that mostly above the root of the nose.

MONOHEMERA. (From movos, single, and ημεςα, a day.) A disease of one day's continuance.

The intestinum ca-Monomachon. cum.

(From moves, single, and MONOPEGIA. συγνυμι, to compress. A pain in only one side of the head. MONOPIA. (From μονος, single, and ωφ,

the eye.) See Monoculus.

Mononchis. (From μονος, one, and οξχις, a testicle.) An epithet for a person that has but one testicle.

Mons. A mount, or hill.

MONS VENERIS. The triangular child being born perfect, had such a power

eminence immediately over the os pub women, that is covered with hair.

MONSTER. Lusus natura. man divides monsters into, 1st, Monsters from redundance or multiplicity of parts; 2d, Monsters from deficiency or want of parts; 3d, Monsters from confusion of

parts.

To these might perhaps be added, without impropriety, another kind, in which there is neither redundancy, nor deficiency, nor confusion of parts, but an error of place, as in transposition of the viscera. But children born with diseases, as the hydrocephalus, or their effects, as in some cases of blindness, from previous inflammation, cannot be properly considered as monsters, though they are often so denominated.

Of the first order there may be two kinds, redundance or multiplicity of natural parts, as of two heads and one body, of one head and two bodies, an increased number of limbs, as legs, arms, fingers, and toes; or excrescences or additions to parts of no certain form, as those upon the head and other parts of the body, not surprising that we should be ignorant also of the manner in which monsters or irregular births are generated or produced; though it is probable that the laws by which these are governed are as regular, both as to cause and effect, as in common or natural productions. Formerly, and indeed till within these few years, it was a generally-received opinion, that monsters were not primordial or aboriginal, but that they were caused subsequently, by the power of the imagination of the mother, transferring the imperfection of some external object, or the mark of something for which she longed, with which she was not indulged, to the child of which she was pregnant; or by some accident which happened to her during her pregnancy. Such opinions, it is reasonable to think, were permitted to pass current, in order to protect pregnant women from all hazardous and disagreeable occupations, to screen them from severe labour, and to procure for them a greater share of indulgence and tenderness than could be granted to them in the common occurrences of life. The laws and customs of every civilized nation have, in some degree, established a persuasion that there was something sacred in the person of a pregnant woman: and this may be right in several points of view; but these go a little way towards justifying the opinion of monsters being caused by the imagination of the mother. The opinion has been disproved by common ohservation, and by philosophy, not perhaps by positive proofs, but by many strong negative facts; as the improbability of any

existed; the freedom of children from any blemish, their mothers being in situations most exposed to objects likely to produce them; the ignorance of the mother of any thing being wrong in the child, till, from information of the fact, she begins to recollect every accident which happened during her pregnancy, and assigns the worst, or the most plausible, as the cause; the organization and colour of these adventitions substances; the frequent occurrence of monsters in the brute creation, in which the power of the imagination cannot be great; and the analogous appearances in the vegetable system, where it does not exist in any degree. Judging, however, from appearances, accidents may perhaps be allowed to have considerable influence in the production of monsters of some kinds, either by actual injury upon parts, or by suppressing or deranging the principle of growth, because, when an arm, for instance, is wanting, the rudiments of the deficient parts may generally be discovered.

MORBILLI. (Dim. of morbus, a dis-

ease.) See Rubeola.

MORBUS ANQUATUS. The jaundice.
MORBUS ATTONITUS. The epilepsy.
MORBUS GALLICUS. The venereal disease.

Monnus infantilis. The epilepsy.

Monnus infantilis. The epilepsy.

Mornus Indicus. The Indian disease, the venereal disease.

Monbus MAGNUS. The epilepsy.

The black disease. Monbus Nigen. So Hippocrates named it, and thus described it. This disorder is known by vomiting a concrete blood of a blackish red colour, and mixed with a large quantity of insipid, acid, or viscid phlegm. This evacuation is generally preceded by a pungent tensive pain, in both the hypoeliondria; and the appearance of the disease is attended with anxiety, a compressive pain in the præcordia, and fainting, which last is more frequent and violent, when the blood which is evacuated is fætid and corrupt. The stomach and the spleen are the principal, if not the proper seat of this disease.

MORBUS SACER. The paindice. MORBUS SACER. The epilepsy.

Morei. Phallus esculentus of Linnaus. It grows on moist banks and wet pasture, and springs up in May. It is used in the same manner as the truffle, for gravies and stewed dishes, but gives an inferior flavour.

Moneros. (From morum, the mulberry.)

A decoction of mulberries.

Monta. (From pages, foolish.) Idiotism. Fatuity.

Mono. (From morom, a mulberry.) 3 small absects resembling a mulberry.

Monosis. (From μοζος, folly.) See

Morrhea alba. (From μοςφη, form.) A species of cutaneous leprosy. See Alphus. Morsellus. Morsulus. A lozenge.

, Morsuli. An ancient name for those forms of medicines which were to be chewed in the mouth, as a lozenge, the word signifying a little mouthful.

MORTUS DIABOLI. The frimbrize of the

Fallopian tubes.

MORTA. See Pemphigus.

MORTARIOLUM. (Dim. of mortarium, a mortar.) In chymistry, it is a sort of mould for making cupels with, also a little mortar. In anatomy, it is the sockets of

the teeth.

MORTIFICATION. (From mors, death, and fo, to become.) Mortificatio. Gangrena. Sphacelus. The loss of vitality of a part of the body. Surgeons divide mortification into two species, the one preceded by inflammation, the other without it. In inflammations that are to terminate in mortification, there is a diminution of power joined to an increased action; this becomes a cause of mortification, by destroying the balance of power and action, which ought to exist in every part. There are, however, cases of mortification that do not arise wholly from that as a cause: of this kind are the carbuncle and the slough, formed in the small-pox pustule. Healthy phlegmonous inflammation seldom ends in mortification, though it does so when very vehement and extensive. Erysipelatous inflammation is observed most frequently to terminate in gangrene; and whenever phlegmon is in any degree conjoined with an erysipelatous affection, which it not unfrequently is, it seems thereby to acquire the same tendency, being more difficult to bring to resolution, or suppuration, than the true phlegmon, and more apt to run into a mortified

Causes which impede the circulation of the part affected, will occasion mortification, as is exemplified in strangulated hernia, tied polypi, or a limb being deprived of circulation from a dislocated joint.

Preventing the entrance of arterial blood into a limb, is also another cause. Paralysis, conjoined with pressure, old age, and ossification of the arteries, may produce mortification; also cold, with the sudden application of warmth, and likewise ex-

cessive heat applied to a part.

The symptoms of mortification that take place after inflammation are various, but generally as follows:—the pain and sympathetic fever suddenly diminish, the part affected becomes soft, and of a livid colour, losing at the same time more or less of its sensibility.

When any part of the body loses all motion, sensibility, and natural heat, and becomes of a brown livid or black colour, it is said to be affected with sphacelus. When the part becomes a cold, black, fibrous, senseless substance, it is termed a slough. As long as any sensibility, motion, and warmth continue, the state of the disorder is said to be gangrone. This last term is synonymous with mortification.

When gangrene takes place, the patient is usually troubled with a kind of hiccough: the constitution always suffers an immediate dejection, the countenance assumes a wild cadaverous look, the pulse becomes small, rapid, and sometimes irregular; cold perspirations come on, and the patient is often affected with diarrhoza and deli-

rium.

MORUM. The mulberry. The tree that affords this fruit is the Morus nigra; foliis cordatis scabris of Linnaus. berries abound with a deep violet coloured juice, which, in its general qualities, agrees with that of the fruits called acido dulces, allaying thirst, partly by refrigerating, and partly by exciting an excretion of mucus from the mouth and fauces, a similar effect is also produced in the stomach, where, by correcting putrescency, a powerful cause of thirst is removed. The London College directs a syrupus mori, which is an agreeable vehicle for various medicines. The bark of the root of this tree is said, by Andrée, to be uscful in cases of tænia.

MORUS. The name of a genus of plants in the Linnman system. Class, Monecia. Order, Tetandria. The mulberry.

tree.

Morus Nigra. The systematic name of the mulberry-tree. See Morum.

Moschata Nux. See Nux moschata. (Mosch, Arab.) MOSCHUS. Musk. An unctuous substance, contained in excretory follicles about the navel of the male called moschus moschiferus by animal Linnæus, a ruminating quadruped, resembling the antelope, from which it does not differ sufficiently to form a particular genus; the strong and permanent smell of which is peculiar to it. It is contained in a bag placed near the umbilical region. The best musk is brought from Tonquin, in China; an inferior sort from Agria and Bengal, and a still worse from Russia.

It is slightly unctuous, of a black colour, having a strong durable smell and a bitter taste. It yields part of its active matter to water, by infusion; by distillation the water is impregnated with its flavour, alkohol dissolves it, its impurities excepted. Chewed, and rubbed with a knife on paper, it looks bright, yellowish, smooth, and free from grittiness. Laid on a red-hot iron, it catches flame and burns almost

entirely away, leaving only an exceeding small quantity of light greyish ashes. If any earthy substances have been mixed with the musk the impurities will discover them. The medicinal and chymical properties of musk and castor are very similar: the virtues of the former are generally believed to be more powerful, and hence musk is preferred in cases of imminent danger. It is prescribed as a powerful antispasmodic, in doses of three grains or upwards, even to half a drachm, in the greater number of spasmodic diseases, especially in hysteria and singultus, and also in diseases of debility. In typhus, it is employed to remove subsultus tendinum, and other symptoms of a spasmodic nature. In cholera it frequently stops vomiting, and, combined with ammonia, it is given to arrest the progress of gangrenc. It is best given in the form of bolus. To children it is given in the form of enema, and is an efficacions remedy in the convulsions arising from dentition. It is also given in hydrophobia, and in some forms of ma-

Moschus Moschifenus. The systematic name of the musk animal. See Moschus.

Mosquita. (From mosquita, a gnat, Span.) An itching eruption of the skin, produced in hot climates by the bite of gnats.

Mossyllum. (Mosundov.) The best cin-

namon.

tion.

Mother of thyme. Sec Serpyllum. Motherwort. See Cardiaca.

MOTORH OCULORUM. (Nervi Motorii; so called from their office.) The third pair of nerves of the brain. They arise from the crura cerebii, and are distributed on the muscles of the builb of the eye.

Mould. See Fontanella.

Mountain parsley, black. See Oreoseli-

Mouse-par. See Pilosella.

MOUTH. Os. The cavity of the mouth is well known. The parts which constitute it are the common integuments, the lips, the muscles of the upper and under jaw, the palate, two alveolar arches, the gums, the tongue, the checks, and salival glands. The bones of the mouth are the two superior maxillary, two palatine, the lower jaw, and thirty-two teeth. The arteries of the external parts of the mouth are granches of the infra-orbital, inferior alveolar, and fascial arteries. The vens empty themselves into the external jugulars. The nerves are branches from the fifth and seventh pair. The use of the mouth is for

tion, suction, and taste.

MOXA JAPONICA. (Japonese.) Artemesia Chinensis. Musia pattræ. Moxa. Mugwort of China. A soft lanuginous substance, prepared in Japan, from the young leaves of a species of mugwort, by beating tnem when thoroughly dried, and rubbing them betwixt the hands, till only the fine fibres are left. Moxa is celebrated in the eastern countries for preventing and curing many disorders, by being burnt on the skin; a little cone of it laid upon the part, previously moistened, and set on fire on the top, burns down with a temperate and glowing heat, and produces a darkcoloured spot, the ulceration of which is promoted by putting a little garlic, and the ulcer is either healed up when the eschar separates, or kept running for a length of time, as different circumstances may require.

MUCILAGE. Mucilago. A solution

of gum. See Gum.

MUCILAGINOUS EXTRACTS. Extracts that readily dissolve in water, scarcely at all in spirits of wine, and undergo

spirituous fermentation.

Mucilage of aca-MUCILAGO ACACIÆ. cix. Mucilago gummi arabici. " Take of heat or cold. acacia gum, powdered, four ounces; boiling water, half a pint." Rub the gum with the water, until it incorporates into a mucilage. A demulcent preparation, more frequently used to combine medicines, than in any other form.

MUCILAGO ANYLI. Starch mucilage. " Take of starch, three drachms; water, a pint." Rub the starch, gradually adding the water to it; then boil until it incorporates into a mucilage. This preparation is mostly exhibited with opium, in the form of clysters, in diarrhoas and dysenteries, where the tenesmus arises from an abrasion of the mucus of the rectum.

See Mu-MUCILAGO ARABICI GUMMI.

cilago acaciæ.

MUCILAGO SEMINIS CYDONII. See De-

coctum cydonii.

Mucilage MUCILAGO TRAGACANTHE. of tragacanth joined with syrup of mulberries, this forms a pleasant demulcent, and may be exhibited to children, who are fond of it. These two last mucilages are omitted in the last London Pharmacopæia, as possessing no superiority over the mucilage of acacia.

MUCOCARNEUS, In M. A. Severinus, it is an epithet for a tumour, and an abscess, which is partly fleshy and partly mu-

MUCOUS GLANDS. Glandula. mu-Muciparous glands. Glands that secrete mucus, such as the glands of the Schneiderian membrane of the nose, the

mastication, speech, respiration, degluti- glands of the fauces, œsophagus, stomach,

intestines, bladder, urethra, &c. Animal mucus MUCUS, ANIMAL. Animal mucus differs from that obtained from the vegetable kingdom, in not being soluble in water, swamming on its surface; nor capable of mixing oil with water, and being soluble in mineral acids, which vegetable mucus is not. The use of this substance is to lubricate and defend the parts upon which it is secreted, as the nose, æsophagus, stomach, intestines, urethra, vagina, &c. Mr. Everard Home, in his dissertation on the properties of pus, informs us of a curious and apparently decisive mode of distinguishing between pus and animal mucus. The property, he observes, which characterizes pus, and distinguishes it from most other substances, is, its being composed of globules, which are visible when viewed through a microscope; whereas animal mucus, and all chymical combinations of animal substances, appear in the microscope to be made up of flakes. This property was first noticed by the late Mr. J. Hunter.

MUCUS, VEGETABLE. See Gum. Mugwort. See Artemisia vulgaris.

MULE. Pustules contracted either by

Mulberry. See Morum. Mullein. See Verbascum.

MULSUM. Musus. Mulse. Hydromel. Honey-water; though sometimes it signi-

fies wine sweetened with honey.

MULTIFIDUS SPINÆ. (From multus, many, and findo, to divide.) Transverso spinalis lumborum. Musculus sacer. Semispinalis internus, sive transverso-spinalis dor-Semi-spinalis, sive transverso-spinalis colli, pars interna of Winslow. Transversalis lumborum vulgo sacer. Transversalis dorsi. Transversalis colli of Douglas. Lum. bo dorsi spinal of Dumas. The generality of anatomical writers have unnecessarily multiplied the muscles of the spine, and hence their descriptions of these parts are confused, and difficult to be understood. Under the name of multifidus spinæ, Albinus has therefore very properly included. those portions of muscular flesh, intermixed with tendinous fibres, which lie close to the posterior part of the spine, and which Douglas and Winslow have described as three distinct muscles, under the names of transversales, or transverso-spinales, of the loins, back, and neck. The multifidus spinæ arises tendinous and fleshy from the upper convex surface of the os sacrum, from the posterior adjoining part of the illium, from the oblique and transverse processes of all the lumbar vertebræ, from the transverse processes of all the dorsal vertebræ, and from those of the cervical vertebræ, excepting the three first. From all these

origins the fibres of the muscles run in an oblique direction, and are inserted, by distinct tendons, into the spinous processes of all the vertebræ of the loins and back, and likewise into those of the six inferior vertebræ of the neck. When this muscle acts singly, it extends the back obliquely, or moves it to one side; when both muscles act, they extend the vertebræ backwards.

MULTIFORME OS. See Ethmoid bone.

MULTIPES. (From multus, many, and pes, a foot.) 1. The wood-louse. 2. The polypus. 3. Any animal having more than four feet.

Mumps. See Cynanche.

MUNDICATIVA. (From mundo, to cleanse.) Mundificantia. Medicines which purify and clean away foulness.

MUNDIFICANTIA. See Mundicativa.

Mungos. Radix serpentum. This bitter root of the plant Ophiorrhiza mungos of Linnæus is much esteemed in Java, Sumatra, &c. as preventing the effects which usually follow the bite of the naja, a venomous serpent, with which view it is eaten by them. It is also said to be exhibited medicinally in the cure of intestinal worms.

MURALIS. (From murus, a wall; so called because it grows upon walls.) Pelli-

tory. See Parietaria.

MURARIA. (From murus, a wall; because it grows about walls.) A species of maiden hair.

MURIAS. A muriate, or salt, formed by the union of the muriatic acid with certain basas, as muriate of ammonia, &c.

MURIAS AMMONIACÆ monia muriata, and Sal ammoniac.

MURIAS BARYTÆ. Terra ponderosa salita. The muriate of barytes, or heavy earth, is a very acrid and poisonous preparation. In small doses it proves sudorific, diuretic, deobstruent, and atterative; in an over-dose, emetic, and violently purgative. The late Dr. Crawford found it very serviceable in all diseases connected with scrophula; and the Germans have employed it with great success in some diseases of the skin and viscera, and obstinate ulcers. The dose of the saturated solution in distilled water, is from five to fifteen drops for children, and from fifteen to twenty for adults.

MURIAS CALCIS. Calx salita. Sal ammoniacus fixus. This preparation is exhibited with the same views as the muriate of barytes. It possesses deobstruent, diuretic, and cathartic virtues, and is much used by the celebrated Fourcroy against scrophula, and scrophulous diseases. Six, twelve, and twenty grains, are given to children three times a day, and a drachm

to adults.

MURIAS FERRI. Ferrum salitum.

Olum martis per deliquium. This preparation of iron is styptic and tonic, and may be given in chlorosis, intermittents, rachitis, &c.

MURIAS FERRI AMMONIACALIS. See Ferrum ammoniatum.

MURIAS HYDRARGYRI. There are two simple muriates of mercury. See Submurias hydrargyri, and Oxymurias hydrargy-

MURIAS HYDRARGYRI AMMONIACALIS. See Hydrargyrus precipitatus albus.

MURIAS HYDRARGYRI OXYGENATUS. Sec

oxymurias Hydrargyri.

MURIAS HYPEROXYGENATUS PO-TASSÆ. The oxygenated nouriate of potash has lately been extolled in the cure of the venereal disease. It is exhibited in doses of from fifteen to forty grains in the course of a day. It increases the action of the heart and arteries, oxygenates the blood, and proves of great service in scorbutus, asthenia, and cachectic diseases.

Alkali vegeta-MURIAS POTASSÆ. bile salitum. Sal digestivus. Sal febrifugus Sylvii. This salt is exhibited with the same intention as the muriate of soda, and was formerly in high estimation in the cure of

intermittents, &c.

MURIAS SODÆ, Muriate of soda. Alkali minerale salitum. Sal communis. Sal culinaris. Sal fontium. Sal gemmæ. marinus. Natron muriatum. Soda muriata. Common culinary salt. This salt is more abundant in nature than any other. It is found in prodigious masses in the internal part of the earth, in Calabria, in Hungary, in Muscovy, and more especially Weilicska, in Poland, near Mount Capax, where the mines are very large, and afford immense quantities of salt. It is also obtained by several artificial means from sea-water. It possesses antiseptic, dinretic, and resolvent qualities, and is frequently employed in form of clyster, fomentation, lotion, pediluvium, and bath, in obstipation, against worms, gangrene, scrophulous, tumours, herpetic eruptions, arthritis, &c.

MURIAS STIBII HYPEROXYGENATUS.

Antimonium muriatum

MURIATIC ACID GAS. The basis of this gas is still unknown. The presence of oxygen has not been even demonstrated in it, and it is only by analogy that we may venture to suppose it instrumental in this acid gas.

Properties .-- It has a very pungent and suffocating odour, which excites coughing. It is readily absorbed by water, by ardent spirit, ether, fat and essential oils, melted wax, phosphorus, and many other bodies. It is a true acid. It suffocates animals, and is so very caustic as to excoriate the skin. It extinguishes a lighted taper, the flame of which becomes green, or rather light

MUR

tube becomes filled with dense white vapours, which are muriatic acid gas, con-densed again by means of the moisture of the atmosphere. The sulphuric acid, added to the muriatic acid, deprives the latter of part of its water, a combination and penetration of the two liquids take place, and caloric is evolved, contributing to render

the gas aëriform, which is thus forced to escape. This experiment proves that the affinity of sulphuric acid for water is greater than

that of muriatic acid.

Water impregnated with this gas forms MURIATIC ACID.

Properties.-Liquid muriatic acid, or water impregnated with muriatic acid gas, is a colourless, very oderous, and pungent fluid. It emits copious white fumes in contact with moist atmospheric air; these fumes are muriatic acid gas that escapes from it, and condenses again by combining with the humidity of the air. If a widemouthed bottle, containing strong muriatic acid, be opened, and the hand brought near its orifice, a sensible warmth is perceived, which arises from the combination of the acid gas with the water of the atmosphere. Liquid muriatic acid is unal-terable by any known combustible body. It disengages the carbonic, phosphoric, and sulphureous acids from all their combinations, but it is constantly expelled by the action of the sulphuric acid.

Method of obtaining Muriatic Acid .- Muriatic acid is best obtained by decomposing muriate of soda, or common salt, by means of sulphuric acid, in the following

manner:

Put into a tubulated retort, lodged in a connected with Pepy's distillatory vessel, or Woulf's bottles, every one containing a small quantity of distilled water, three parts of muriate of soda, and pour on it one of sulphuric acid very gradually, or rather let it be suffered to drop into the retort, by means of a funnel fastened to its tubulure, and whose inner opening may at pleasure be closed, wholly or in part, by means of a ground-glass rod. Muriatic acid gas will be plentifully disengaged, which passes through the neck of the retort, and becomes absorbed by the water. When the water in the first bottle is fully saturated, it absorbs no more, and becomes cold, butthe gas continues to pass into the next bottles, and heats the water they contain. The water, thus impregnated with muriatic acid gas, is muriatic acid.

Remark.-If sulphuric acid, diluted with an equal quantity, by weight, of water, be made use of in this process, the apparatus of Pepys or Woulf may be dispensed with,

blue, at the upper part of its disk. Light effervesence takes place, and the whole has no effect upon it. Caloric rarifies it. It is heavier than common air. The specific gravity of the former is to that of the latter as 1.750 to 1.000. When brought into contact with atmospheric air, or oxygen gas, it forms a white cloud. Ice is melted by it as speedily as if thrown into the fire. It unites to alkaline and terrene substances, and forms with them new compounds. It has no action on siliceous earths. It combines with alumine and magnesia. It absorbs oxygen, when in the state of gas, feebly, though there are methods of uniting them readily. If ammoniacal gas be mixed with it, and heat applied, both gases lose their gazeous form in a moment, and are transformed to a concrete salt. Carbonic acid gas, nitrogen, gas, gazeous oxyd of nitrogen, sulphurated hydrogen gas, and carbonated hydrogen gas, have no action upon it. It has never been found in a disengaged state in nature. When electric explosions are made to pass through it, its bulk is diminished and hydrogen gas is evolved. These changes are owing to a quantity of water contained in the gas, and cease when it is deprived of moisture, as has been proved by Mr. Henry.

Method of obtaining Muriatic Acid Gas -1. By decomposing muriate of soda, by means of sulphuric acid. For this purpose, put into a turbulated retort two parts of very dry muriate of soda, and pour on it gradually one part of concentrated sulphuric A violent action takes place and muriatic acid gas becomes liberated, which must be collected over mercury in the usual manner. The sulphuric acid has a greater affinity for the soda than the muriatic acid has, it therefore unites to it and forms sulphate of soda. The muriatic acid, being sand-heat, or supported over a lamp, and liberated, takes the gazeous form, and appears as muriatic acid gas, and as the decomposition takes place very rapidly, it is not necessary to apply heat, until the disengagement of the gas begins to slacken, after which the further extrication may be

assisted by the heat of a lamp.

2. Muriatic acid gas may likewise be obtained by expelling it from its combination with water.

For this purpose put concentrated muriatic acid into a retort, immerse the beak of it under a receiver placed in a mercurial pneumatic trough, and filled with that On exposing the acid to a gentle heat, muriatic acid gas will be obtained. If the process be very carefully managed, nothing but water remains in the retort.

3. Muriatic acid gas is likewise produced by putting any quantity of liquid muriatic acid into a long glass tube, and adding to it about one-third or one-fourth by measure of concentrated sulphuric acid. A violent

MUR

and a common receiver may be used with

The salts formed by the combination of muriatic acid with different bases, are called

MURIATES. This acid possesses active tonic powers, In typhus, or nervous fevers, although employed on the Continent with success, and used in very liberal quantities in this country, is apt to determine to the bowels. the fevers of children, the oxymuriatic acid is said frequently to act as a specific. ternally, the muriatic acid has been applied in the form of a bath, to the feet, in gout. In a late publication, there are accounts of its successful application as a lithontriptic.

Muriatic acid, oxygenated. See Oxyge-

nated muriatic acid.

Musadi. Sal ammoniac.

Musa paradistaca. Musa. Palma hu-Ficus Indica. Bala. uilis. Platanus. The plantain-tree. It grows spontaneously in many parts of India, but has been immemorially cultivated by the Indians in every part of the continent of South-America. It is an herbaceous tree, growing to the height of fifteen or twenty feet. The fruit are nearly of the size and shape of ordinary cucumbers, and, when ripe, of a pale yellow colour, of a mealy substance, a little clammy, a sweetish taste, and will dissolve in the mouth without chewing. The whole spike of fruit often weighs forty or fifty pounds. When they are brought to table by way of desert, they are either raw, fried, or roasted; but, if intended for bread, they are cut before they are ripe, and are then either roasted or boiled. trees being tall and slender, the Indians cut them down to get at the fruit; and in doing this they suffer no loss, for the stems are only one year's growth, and would die if not cut; but the roots continue, and new stems soon spring, up which in a year produceripe fruit also. From the ripe plantains they make a liquor called mistaw. When they make this, they roast the fruit in their husks, and, after totally beating them to a mash, they pour water upon them, and, as the liquor is wanted, it is drawn off. the nature of this fruit is such, that they will not keep long without running into a state of putrefaction; and therefore, in order to reap the advantage of them at all times, they make cakes of the pulp, and dry them over a slow fire, and, as they stand in need of mistaw, they mash the cakes in water, and they answer all the purposes of fresh fruit. The cakes are exceedingly convenient to make this liquor in their journeys, and they never fail to carry them for that purpose The leaves of the tree being large and spacious, serve the Indians for table-cloths and napkins.

MUSA SAPIENTUM. The systematic name of the banana-tree. See Banana.

Muscipala. (From mus, a mouse, and capio, to take, so called from its viscidity. by which flies are caught as with bird-lime.)

A species of lychnis.

MUSCLE. Musculus. The parts that are usually included under this name consist of distinct portions of flesh, susceptible of contraction and relaxation; the motions of which, in a natural and healthy state, are subject to the will, and for this reason they are called voluntary muscles. Besides these, there are other parts of the body that owe their power of contraction to their muscular fibres: thus the heart is a muscular texture, forming what is called a hollow muscle; and the urinary bladder, stomach, intestines, &c. are enabled to act upon their contents, merely because they are provided with muscular fibres; these are called involuntary muscles, because their motions are not dependent on the will. The muscles of respiration being in some measure influenced by the will. are said to have a mixed motion. The names by which the voluntary muscles are distinguished are founded on their size, figure, situation, use, or the arrangement of their fibres, or their origin and insertion; but, besides these particular distinctions, there are certain general ones that require to be noticed. Thus, if the fibres of a muscle are placed parallel to each other, in a straight direction, they form what anatomists term a rectilinear muscle; if the fibres cross and intersect each other, they constitute a compound muscle; when the fibres are disposed in the manner of rays, a radiated muscle; when they are placed obliquely with respect to the tendon, like the plume of a pen, a penniform muscle. Muscles that act in opposition to each other are called antagonists; thus every extensor has a flexor for its antagonist, and vice versa. Muscles that concur in the same action are termed congeneres. The muscles being attached to the bones, the latter may be considered as levers, that are moved in different directions by the contraction of those organs. That end of the muscle which adheres to the most fixed part is usually called the origin; and that which adheres to the more moveable part the insertion of the muscle. In almost every muscle two kinds of fibres are distinguished; the one soft, of a red colour, sensible, and irritable, called fleshy fibres, see Muscular Fibres; the other of a firmer texture, of a white glistening colour, insensible, without irrritability or the power of contracting, and named tendinous fibres. They are occasionally intermixed, but the fleshy fibres generally prevail in the belly, or middle part of the muscle, and the tendinous ones in the extremities. If these tendinous fibres are formed into a round slender cord, they form what is called the

tendon of the muscle; on the other hand, if they are spread into a broad flat sur-

face, it is termed an aponeurosis.

Each muscle is surrounded by a very thin and delicate covering of cellular membrane, which encloses it as it were like a sheath, and, dipping down into its substance, surrounds the most minute fibres we are able to trace, connecting them to each other, lubricating them by means of the fat which its cells contain in more or less quantity in different subjects, and serving as a support to the blood-vessels, lymphatics, and nerves, which are so plentifully distributed through the muscles .-This cellular membrane, which in no respect differs from what is found investing and connecting the other parts of the body, has been sometimes mistaken for a membrane peculiar to the muscles; and hence we often find writers giving it the name of membrana propria musculosa. The muscles owe the red colour, which so particularly distinguishes their belly part, to an infinite number of arteries, which are every where dispersed through the whole of their reticular substance; for their fibres, after having been macerated in water, are (like all other parts of the body divested of their blood) found to be of a white co-These arteries usually enter the muscles by several considerable branches, and ramify so minutely through their substance, that we are unable, even with the best microscopes, to trace their ultimate branches. Ruysch fancied that the muscular fibre was hollow, and a production of a capillary artery; but this was merely conjectural. The veins, for the most part, accompany the arteries, but are found to be larger and more numerous. The lymphatics, likewise, are numerous, as might be expected from the great proportion of reticular substance, which is every where found investigating the muscular fibres. The nerves are distributed in such abundance to every muscle, that the muscles of the thumb alone are supplied with a greater proportion of nervous influence than the largest viscera, as the liver for instance. They enter the generality of mus-cles by several trunks, the branches of which, like those of the blood-vessels, are so minutely dispersed through the cellular substance, that their number and minuteness soon elude the eye and the knife of the anatomist. This has given rise to a conjecture, as groundless as all the other conjectures on this subject, that the muscular fibre is ultimately nervous.

A Tuble of the Muscles.

The generality of anatomical writers have arranged muscles according to their several uses; but this method is evidently defective, as the same muscle may very often have different and opposite uses. The method here adopted is that more usually followed; they are enumerated in the order in which they are situated, beginning with those that are placed nearest the integuments, and proceeding from these to the muscles that are more deeply scated.

[The reader will be pleased to observe, that all the muscles are in pairs, except

those marked thus\*].

Muscles of the integuments of the cranium:
Occipito frontalis\*. Corrugator supercilii.

Muscles of the eye-lids:
Orbicularis palpebrarum. Levator palpe-

bræ superioris.

Muscles of the eye-ball.

Rectus superior. Rectus inferior. Rectus internus. Rectus externus. Obliquus

superior. Obliquus inferior.

Muscles of the nose and mouth.
Levator palpebra superioris alaque nasi.
Levator labii superioris proprius. Levator anguli oris. Zygomaticus major. Zygomaticus minor. Buccinator. Depressor anguli oris. Depressor labii inferioris, Orbicularis oris. Depressor labii superioris alaque nasi. Constrictor nasi, Levator menti vel labii inferioris,

Muscles of the external ear.

Superior auris. Anterior auris. Posterior auris. Helicis major. Helicis minor. Tragicus. Antitragicus. Transversus auris.

Muscles of the internal ear.

Laxator tympani. Membrana tympani.

Tensor tympani. Stapedius.

Muscles of the lower jaw.

Temporalis, Musseter. Pterygoideus externus. Pterygoideus internus.

Muscles about the anterior part of the

neck:
Platysma myoides. Sterno-cleidomastoi-

Platysma myoides. Sterno-cleidomastoideus.

Muscles between the lower jaw and os

hyoides:
Digastricus. Mylo-hyoideus. Genio-hyoideus. Genio-glossus. Hyo-glossus. Lin-

gualis.
Muscles situated between the os hyoides and
trunk:

Sterno-hyoideus. Crico-hyoideus. Sterno-thyroideus. Thyreo-hyoideus. Crico-thyroideus.

Muscles between the lower juw and os hyoides laterally:

Stylo-glossus, Stylo-hyoideus, Stylo-pharyngeus, Circumflexus, Levator palati mollis,

Muscles about the entry of the fauces.
Constrictor isthmi faucium. Palatopharyngeus. Azygos uvulæ\*.

Muscles situated on the posterior part of the pharynx:

Constrictor pharyngis superior. Constric-

tor pharyngis medius. Constrictor pharyngis inferior.

Muscles situated about the glottis:

Crico-arytænoideus posticus. Črico-arytænoideus laterallis. Thyreo-arytænoideus. Arytænoideus Obliquus\*. Arytænoideus transversus\*. Thyreo-epiglottideus. Arytæno-epiglottideus.

Muscles situated about the anterior part of

the abdomen:

Obliquus descendens externus. Obliquus ascendens internus. Transversalis abdominis. Rectus abdominis. Pyramidalis.

Muscles about the male organs of genera-

tion:

Dartos\*. Cremaster. Erector penis. Accelerator urinæ. Transversus perenei.

Muscles of the anus:

Sphincter ani\*. Levator ani\*.

Muscles of the female organs of generation:

Erector clitoridis. Splincter vaginæ\*.

Muscles situated within the pelvis:

Obturator internus. Coccygeus.

Muscles situated within the cavity of the abdo-

men :

Diaphragma\*. Quadratus lumborum. Psoas parvus. Psoas magnus. Iliacus internus.

Muscles situated on the anterior part of the

thorax:

Pectoralis major. Subclavius. Pectoralis minor. Serratus major anticus.

Muscles situated between the ribs, and within

the thorax:

Intercostales externi. Intercostales interni. Triangularis.

Muscles situated on the anterior part of the neck, close to the vertebræ:

Longus colli. Rectus internus capitis major Rectus capitis internus minor. Rectus capitis lateralis.

Muscles situated on the posterior part of the

trunk:

Trapezius. Latissimus dorsi, Serratus posticus inferior. Rhomboideus. Splenius. Serratus superior posticus. Spinalis dorsi. Levatores costarum. Sacro-lumbalis. Longissimus dorsi. Complexus. Trachelo-mastoideus. Levator scapulæ. Semi-spinalis dorsi. Multifidus spinæ. Semi-spinalis colli. Transversalis colli. Rectus capitis posticus minor. Obliquus capitis superior. Obliquus capitis inferior. Scalenus. Interspinales. Intertransversales.

Muscles of the superior extremities:
Supra-spinatus, Infra-spinatus, Teres
minor, Teres major, Deltoides, Coraco-

brachialis. Subscapularis.

Muscles situated on the os humeri:

Biceps flexor cubiti. Brachialis internus.
Biceps extensor cubiti. Anconcus.

Muscles situated on the fore arm:
Supinator radii longus. Extensor carpi radialis longior. Extensor carpi radialis brevior. Extensor digitorum communis. Ex-

tensor minimi digiti. Extensor carpi uluaris. Flexor carpi uluaris. Palmaris longus. Flexor carpi radialis. Pronator radii teres. Supinator radii brevis. Extensor osis metacarpi pollicis manus. Extensor primi internodii. Extensor secundi internodii. Indicator. Flexor digitorum sublimis. Flexor digitorum profundus. Flexor longus pollicis. Pronator radii quadratus.

Muscles situated chiefly on the hand:

Lumbricales. Flexor brevis pollicis manus. Opponens pollicis. Abductor pollicis manus. Adductor pollicis manus. Abductor indicis manus. Palmaris brevis. Abductor minimi digiti manus. Adductor minimi digiti. Flexor parvus minimi digiti. Interossei interni. Interossei externi.

Muscles of the inferior extremities:
Pectinalis. Triceps adductor temoris. Obturator externus. Gluteus maximus. Gluteus minimus. Gluteus medius. Pyriformis. Gemini. Quadratus femoris.

Muscles situated on the thigh:

Tensor vaginæ femoris. Sartorius. Rectus femoris. Vastus externus. Vastus internus. Cruralis. Semi-tendinosus. Semi-membranosus. Biceps flexor cruris. Popliteus.

Muscles situated on the leg :

Gastrocnemius externus. Gastrocnemius internus. Plantaris. Tibialis anticus. Tibialis posticus. Peroneus longus. Peroneus brevis. Extensor longus digitorum pedis. Extensor proprius pollicis pedis. Flexor longus digitorum pedis. Flexor longus pollicis pedis.

Muscles chiefly situated on the foot:

Extensor brevis digitorum pedis. Flexor brevis digitorum pedis. Lumbricalis pedis. Flexor brevis pollicis pedis. Abductor pollicis pedis. Adductor pollicis pedis. Adductor pollicis pedis. Flexor brevis minimi digiti pedis. Flexor brevis minimi digiti pedis. Transversales pedis. Interossei pedis externi. Interossei pedis interni.

MUSCULAR FIBRE. The fibres that compose the body of a muscle are disposed in fasciculi, or bundles, which are easily distinguishable by the naked eye; but these fasciculi are divisible into still smaller ones; and these again are probably subdivisible ad infinitum. The most minute fibre we are able to trace seems to be somewhat plaited; these plaits disappearing when the fibre is put upon the stretch, seem evidently to be the effect of contraction, and have probably induced some writers to assert, that the muscular fibre is twisted or spiral. Various have been the opinions concerning the structure of these fibres; they are all of them founded only on conjecture, and therefore we shall mention only the principal ones, and this with a view rather to gratify the curiosity of the reader, than to afford him information. Borelli supposes them to be so many hol-

MUS

low cylinders, filled with a spongy medullary substance, which he compares to the pith of elder, spongiosa ad instar sambuci. These cylinders, he contends, are intersected by circular fibres, which form a chain of very minute bladders. This hypothesis has since been adopted by a great number of writers, with certain variations. Thus, for instance, Borelli supposes the vesicles to be of a rhomboidal shape; whereas Bernouilli contends that they are oval. Cowper went so far as to persuade himself that he had filled these cells with mercury; a mistake, no doubt, which arose from its insinuating itself into some of the lymphatics. It is observable, however, that Leeuwenhoeck says nothing of any such vesicles. Here, as well as in many other of her works, Nature seems to have drawn a boundary to our inquiries, beyond which no human penetration will probably ever extend. It is surely more commendable, however, to acknowledge our ignorance, than to indulge ourselves in chimæra.

MUSCULAR MOTION. Muscular motions are of three kinds; namely voluntary, involuntary, and mixed. The voluntary motions of muscles are such as proceed from an immediate exertion of the active powers of the will: thus, the mind directs the arm to be raised or depressed, the knee to be bent, the tongue to move, &c. The involuntary motions of muscles are those which are performed by organs, seemingly of their own accord, without any attention of the mind, or consciousness of its active power: as the contraction and dilatation of the heart, arteries, veins, absorbents, stomach, intestines, &c. The mixed motions are those which are in part under the controll of the will, but which ordinarily act without our being conscious of their acting: as is perceived in the muscles of respiration, the intercostals, the abdominal muscles, and the diaphragm.

When a muscle acts, it becomes shorter and thicker; both its origin and insertion are drawn towards its middle. The sphincter muscles are always in action: and so likewise are antagonist muscles, even when they seem at rest. When two antagonist muscles move with equal force, the part which they are designed to move remains at rest; but if one of the antagonist muscles remains at rest, while the other acts, the part is moved towards the centre of motion.

All the muscles of living animals are constantly endeavouring to shorten themselves.

When a muscle is divided it contracts. If a muscle be stretched to a certain extent, it contracts, and endeavours to acquire its former dimensions as soon as the stretching cause is removed: this takes place in the dead body; in muscles cut out of the body; and also in parts not muscular, and is called by the immortal Haller vis mortua, and by some vis elastica. It is greater in living than in dead bodies, and is called the tone of the muscles.

When a muscle is wounded, touched, or otherwise irritated, it contracts, independent of the will: this power is called irritability, and by Haller vis insita; it is a property peculiar to and inherent in the mus-The parts of our body which possess this property are called irritable, as the heart, arteries, muscles, &c. to distinguish them from those parts which have no mus-cular fibres. With regard to the degree of this property peculiar to various parts, the heart is the most irritable, then the stomach and intestines; the diaphragm, the arteries, veins, absorbents, and at length the various muscles follow; but the degree of irritability depends upon the age, sex, temperament, mode of living, climate, state of health, idiosyncrasy, and likewise upon the nature of the stimulus.

When a muscle is stimulated, either through the medium of the will or any foreign body, it contracts, and its contraction is greater or less in proportion as the stimulus applied is greater or less. The contraction of muscles is different accord-ing to the purpose to be served by their contraction: thus, the heart contracts with a jerk; the urinary bladder, slowly and uniformly; puncture a muscle, and its fibres vibrate; and the abdominal muscles act slowly in expelling the contents of the rectum. Relaxation generally succeeds the contraction of muscles, and alternates with

The use of this property is very considerable; for upon it depends all muscular motion, and the function of every viscus, except that of the nerves.

Muscular Power. See Irritability.
MUSCULUS, (a diminutive of mus, a mouse, from its resemblance to a flead mouse.) See Muscle.

See Platysma

Musculus CUTANEUS. my oides.

MUSCULUS FASCIÆ LATÆ. vagina femoris.

MUSCULUS PATIENTIÆ.

MUSCULUS STAPEDIUS. See Stapedius. Musculus supercilii. See Corrugator

supercilii. MI SCULUS TUBE NOVE. See Circum.

MUSCUS. (From μοςχος, tender, so called from its delicate and tender consist-

ence.) Moss.

Muscus arboreus. This plant, Lichen plicatus of Linnaus, we are informed by that great botanist, is applied by the Laplanders to parts which are excoriated by a long journey. It is slightly adstringent

and is applied with that intention to bleeding-vessels.

Muscus caninus. See Lichen cinereus

terrestris.

MUSCUS CLAVATUS. See Lycopodium. MUSCUS CRANII HUMANI. See Usnea.

Muscus cumatilis. This cryptogamious plant, Lichen apthosus, is said to act powerfully on the intestines, though never used in the practice of the present day.

Muscus enectus. Upright club moss. The pharmacopoial name of the Lycopodium selago of Linnaus. The decoction of this plant acts violently as a vomit and a purgative, and was formerly on that account employed to produce abortions.

Muscus Islandicus. See Lichen islandi-

cus.

Muscus maritimus. See Corallinus.

Muscus pulmonarius quercinus. See Pulmonaria arborea.

Muscus fyxidatus. Cup-moss. Musculus pyxoides terrestris. Lichen pyxidatus major. These very common little plants, Lichen cocciferus and pyxidatus of Linnæus, for both are used indifferently, are employed by the common people in this country in the cure of hooping-cough, in the form of decoction.

Muscus squamosus terrestris. See Lycopodium.

MUSIA PATTRE. A name for moxa.

Mushroom. There are several species of the agaricus, which go by the term mushroom; as the agaricus charterellus, deliciosus, violaceos, &c. but that which is eaten in this country is the agaricus campestris of Linnæus. Similar to it in quality is the champignion, or agaricus pratensis. Broiled with salt and pepper, or stewed with cream and some aromatic, they are extremely delicious, and, if not eaten to excess, salubrious. Great care should be taken to ascertain that they are the true fungus, and not those of a poisonous nature. Catchup is made by throwing salt on mushrooms, which causes them to part with their juice.

Musk. See Moschus.

Musk-cranesbill. See Geranium moschatum.

Musk-melon. See Melo.

Musk-seed. See Abelmoschus.

Musaultto. A species of gnat in the West Indies, which produce small tumours on whatever part they settle, attended with so high a degree of itching and inflammation, that the person cannot refrain from scratching, by a frequent repitition of which he not uncommonly occasions them to ulcerate, particularly if the subject is of a robust and full habit.

Mustard, black. See Sinapi. Mustard, hedge. See Erysimum. Mustard, treacle. See Thlaspi. Mustard, mithridate. See Thlaspi. Mustard, yellow. See Sinapi. MUTITAS (From mutus, dumb) Dumbness. A genus of disease in the class locales and order dyscnesiæ of Cullen, which he defines an inability of articulation. He distinguishes three species, vi.

1. Mutitas organica, when the tongue is

removed or injured.

2. Mutitus autonica, arising from an affection of the nerves of the organ.

3. Mutitas surdorum, depending upon being born deaf, or becoming so in their infantile years.

Muza. See Musa.

MYACANTHA. (From  $\mu us$ , a mouse, and  $\alpha x \alpha y \beta x$ , a thorn, so called, because its prickly leaves are used to cover whatever is intended to be preserved from mice.) See Ruscus.

MYAGRO. See Myagrum.

Myagrum. (From μυμα, a fly, and αγρεμο, to seize, because flies are caught by its viscidity.) A species of wild mustard.

Mrce. (From  $\mu\nu\rho$ , to wink, shut up, or obstruct.) 1. It is a winking, closing, or obstruction. It is applied to the eyes, to ulcers, and to the viscera, especially the spleen, where it imports obstructions. 2. In surgery, it is a fungus, such as arises in ulcers and wounds. 3. Some writers speak of a yellow vitriol, which is called Myce.

Michthismos. (From µvζu, to mutter or groan.) In Hippocrates, it is a sort of sighing or groaning during respiration, whilst the air is forced out of the lungs.

MYCONOIDES. (From μυκεα, a noise, and ειδος, a likeness,) applied to an ulcer full of mucus, and which upon pressure emits a wheezing sound.

MYCTER. The nose.

MYCTERES. Μυπτηςες. The nostrils.
MYDESIS. (From μυθαω, to abound with moisture.) It imports, in general, a cor-

ruption of any part from a redundant moisture. But Galen applies it particularly to the eye-lids.

Mynon. (From μυθαω, to grow putrid.)
Fungus or putrid flesh in a fistulous ulcer.

MYDRIASIS. (From μυδαω, to abound in moisture; so named, because it was thought to originate in redundant moisture.) A disease of the iris. Too great a dilatation of the pupil of the eye, with or without a defect of vision. It is known by the pupil always appearing of the same latitude or size in the light. The species of mydriasis are, 1. Mydriasis amaurotica, which, for the most part, but not tways, accompanies an amaurosis. 2. Mydriasis hydrocephalica, which owes its origin to an hydrocephalus internus, or internal dropsy of the ventricles of the cerebrum It is not uncommon amongst children, and is the most certain diagnostic of the disease. 3. Mydriasis verminosa, or a dilatation of

521

the pupil from saburra and worms in the stomach or small intestines. 4. Mudriasis a synechia, or a dilatation of the pupil, with a concretion of the uvea with the capsula of the crystalline lens. 5. Mydriasis paralytica, or a dilated pupil, from a paralysis of the orbicular fibres of the iris: it is observed in paralytic disorders, and from the application of narcotics to the 6. Mydriasis spasmodica, from a spasm of the rectilineal fibres of the iris, as often happens in hysteric and spasmodic diseases. 7. Mydriasis, from atony of the iris, the most frequent cause of which is a large cataract distending the pupil in its passing when extracted. It vanishes in a few days after the operation, in general; a pupil, however long dilated, may remain so from the over and long-continued disten-

MYLACRIS. (From μυλη, a grind-stone, so called from its shape.) The patella, or knee-pan,

MYLE. MUNN. The knee-pan, or a mole

in the uterus.

MYLON. See Staphyloma.

MYLO. Names compounded with this word belong to muscles, which are attached near the grinders; from μυλη, a grinder-tooth: such as,

Mylo-glossi. Small muscles of the

tongue.

MYLO-HYOIDEUS. Mylo-hyoidien of Dumas. This muscle, which was first described by Fallopius, is so called from its origin near the dentes molares, and its insertion into the os hyoides. It is a thin, flat muscle, situated between the lower jaw and the os hyoides, and is covered by the anterior portion of the digastricus. It arises fleshy, and a little tendinous, from all the inner surface of the lower jaw, as far back as the insertion of the pterygoideus internus, or, in other words, from between the last dens molaris and the middle of the chin, where it joins its fellow, to form one belly, with an intermediate tendinous streak, or linea alba, which extends from the chin to the os hyoides, where both muscles are inserted into the lower edge of the basis of that bone. This has induced Riolanus, Winslow, Albinus, and others, to consider it as a single penniform muscle. Its use is to pull the os hyoides upwards, forwards, and to either side.

Mylo-phanyngeus, (Musculus mylofhinyngeus, μυλοφεργλιος; from μυλη, the granding tooth, and φαξυλ<sup>2</sup>, the pharynx.) See Constrictor pharyngeus superior.

MYDERPHALUM. (From MUZ, a fly, and appealog, a head, from its resemblance to the head of a fly.) A tumour in the uvea of the eye.

Myocollitis. (From μυων, a muscle, and κοιλαι, a belly. So Vogel names inflammation of the muscles of the belly.

Myodesofsia. (From μασι, a fly, and α μα, vision.) A disease of the eyes, in which the person sees black spots, an appearance of flies, cobwebs, or black wool, before his eyes.

MYOLOGY. (Myologia, from  $\mu us$ , a muscle, and  $\lambda o \gamma o s$ , a discourse.) The doc-

trine of the muscles.

MYOPIA. (From µvw, to wink, and wf, the eye.) Near-sighted, purblind. The myopes are considered those persons who cannot see distinctly above twenty inches. The myopia is likewise adjudged to all those who cannot see at three, six, or nine inches. The proximate cause is the adunation of the rays of light in a focus before the retina. The species are, 1. Myopia, from too great a convexity of the comea. The cause of this convexity is either from nativity, or a greater secretion of the aqueous humour: hence on one day there shall be a greater myopia than on another. An incipient hydrophthalmia-is the origin of this myopia. 2. Myopia, from too great a longitude of the bulb. This length of the bulb is native, or acquired from a congestion of the humours in the eye; hence artificers occupied in minute .objects, as the engravers of seals, and persons reading much, frequently after puberty become myopes. 3. Myopia, from too great a convexity of the anterior superficies in the crystalline lens. This is likewise from birth. The parallel rays which fall into the cornea, by so much they fall more obliquely, so much the more convex is the cornea, or crystalline lens or vitreous humour in the anterior superficies. But the angle of refraction is equal to the angle of incidence: therefore the angle of refraction so much sooner will be formed as the cornea or lens is more convex. This perfectly accounts for short-sightedness; but an anterior too great convexity of the cornea is the most common cause. 4. Myopia, from too great a density of the cornea, or hu-mours of the eye. Optics teach us by so much sooner the rays of light are forced into a focus, by so much the diaphanous body is denser. 5. Myopia, from a mydriasis or too dilated a pupil; for so much the wider the aperture of the diaphragma is in an optical instrument, so much the nearer is the focus. 6. Myopia infantilis. Infants, from the great convexity of the cornea, are often myopes; but by degrees, as they advance in years, they perceive objects more remotely, by the cornea becoming less convex.

Myors. (From \(\rho\psi\), to wink, and \(\sigma\), the eye.) One who is near-sighted.

MYOSIS. Music. A contraction or too small perforation of the pupil; it is known by vicewing the diameter of the pupil, which is smaller than usual, and remains so in an obscure place, where, natu-

rally, if not diseased, it dilates. It occasions weak sight, or a vision that remains only a certain number of hours in the day; but, if wholly closed, total blindness. species of this disorder are, 1. Myosis spasmodica, which is observed in the hysteric, hypochondriac, and in other spasmodic and nervous affections; it arises from a spasm of the orbicular fibres of the iris. 2. Myosis paralytica arises in paralytic disorders. 3. Myosis inflammatoria, which arises from an inflammation of the iris or uvea, as in the internal ophthalmia, hypopium, or wounded eye. 4. Myosis, from an accustomed contraction of the pupil. This frequently is experienced by those who contemplate very minute objects; by persons who write; by the workers of fine needle-work; and by frequent attention to microscopical inquiries. 5. Myosis, from a defect of the aqueous humour, as after extraction. 6. Myosis nativa, with which infants are born. 7. Muosis naturalis, is a coarctation of the pupil by light, or from an intense examination of minutest These coarctations of the pupil are temporary, and spontaneously vanish.

MYOSITIS. (From μυς, a muscle.) Inflammation of a muscle. It is the term given by Sagar to acute rheumatism.

Myosoris. (Mus, a muscle, and as wros, an ear; so called because its leaves are hairy, and grow longitudinally, like the ear of a mouse.) See Pilosella.

MYOTOMY. (From μυων, a muscle, and τεμνω, to cut.) The dissection of the

muscies.

MYRICA GALE. The systematic name of the Dutch myrtle. See Myrtus brabantica.

Myriophyllon. (From μυρίος, infinite, and φυλλον, a leaf, named from the number of its leaves.) See Millefolium.

MYRISTICA. The name of a genus of plants in the Linnæan system. Class, Dioecia. Order, Monadelphia.

Myristica aromatica. Swartz's name of

the nutmeg-tree.

MYRISTICA MOSCHATA. The systematic name of the tree which produces the nutmeg. See Nux moschata.

MYRISTICA NUX See Nux moschata.

MYRMECIA. (From  $\mu \nu g \mu n \xi$ , a pismire.) A small painful wart, of the size and shape of a pismire. See Myrmecium.

MYRMECIUM A moist soft wart about the size of a lupine, with a broad base, deeply rooted, and very painful. It grows on the palms of the hands and soles of the feet.

MYROCOPUM. (From µugov, an ointment, and µo700, labour.) An unguent to remove lassitude.

Mynobalanus (From μυρος, an ungrows on the eastern coast of Arabia Felix, guent, and εαλανος, a nut, so called be and in that part of Abyssinia which is situ-

cause it was formerly used in ointments.) A myrobalan. A dried fruit, of the plum kind, brought from the East Indies. All the myrobalus have an unpleasant, bitterish, very austere taste, and strike an inky blackness with a solution of steel. They are said to have a gently purgative as well as an astringent and corroborating virtue. In this country they have been long expunged from the pharmacopæias. Of this fruit there are several species.

Myrobalan. This fruit is of a yellowish grey colour, and an irregular roundish or oblong figure, about an inch in length, and three quarters of an inch thick.

MYROBALANUS CHEBULA. The chebule myrobalan. This resembles the yellow in figure and ridges, but is larger, of a darker colour, inclining to brown or blackish, and

has a thicker pulp.

Myrobalanus citrina. Yellow myrobalan. This fruit is somewhat longer than the Belliric, with generally five large longitudinal ridges, and as many smaller between them, somewhat pointed at both ends.

MYROBALANUS EMBLICA. The emblic myrobalan is of a dark blackish grey colour, roundish, about half an inch thick, with six hexagonal faces, opening from one another.

MYROBALANUS INDICA. The Indian or black myrobalan, of a deep black colour, oblong, octangular, differing from all the others in having no stone, or only the rudiments of one, from which circumstance they are supposed to have been gathered before maturity.

Myrobalans. See Myrobalanus.

Myron. (From μυζω, to flow.) An ointment, medicated oil, or unguent.

MYROPHYLLUM. Millefolium aquaticum. Water-fennel. It is said to be vulnerary.

MÝROXYLON. (From μυγον, an ointment, and ξυλον, wood.) The name of a genus of plants in the Linnæan system. Class, Diandria. Order, Monogonia.

MYROXYLON PERUIFERUM. The systematic name of the tree which gives out the Peruvian balsam. See Balsamum Pe-

ruviannm.

MYRRHA. (Myrrha, Heb.) Also called stacte, and the worst sort ergasma. A botanical specimen of the tree which affords this gum-resin has not yet been obtained; but from the account of Mr. Bruce, who says it very much resembles the cacia vera of Linnans, there can be little doubt in refering it to that genus, especially as it corresponds with the description of the tree given of it by Dioscorides. The tree that affords the myrrh, which is obtained by incision, grows on the eastern coast of Arabia Felix, and in that part of Abyssinia which is situ-

(From augres, the

Bruce troglodite. Good myrth is of a clitoris, and gener, a lip.) The nymphæ of bid black red colour, solid and heavy, a peculiar smell, and bitter taste. Its dicinal effects are warm, corroborant, l antisceptic; it has been given as an intenagogue in a dose from 5 to 20 grains; resembling a myrtle-berry. It also means also given in each exies, and applied the clitoris.

MYRTO CHEILIDES.

MYRTUS. (From μυρία, myrrh, because of its smell, or from myrrha, a virgin who was fabled to have been turned into this tree.)

1. The name of a genus of plants in the Linnæan system. Class, Icosandria. Order, Monogynia.

2. The pharmacopæial name of the Myrrhine. The myrtle. Myrtus communis of Linnæus. The berries of this plant are recommended in alvine and uterine fluxes, and other disorders from relaxation and debility. They have a roughish, and not unpleasant taste, and appear to be moderately astringent and corroborant, partaking also of aromatic qualities.

qualities.

Myntus Rrabantica. Myrtus Anglica.

Myrtifolia belgica. Gale. Gagel. Rhus sylvestris. Acaron. Eleagnus. Eleagnus cordo. Chameleagnus dodonæo. The leaves, flowers, and seeds of this plant, Myrica gale of Linnæus, sweet willow, or Dutch myrtle, have a strong fragrant smell, and a bitter taste. They are said to be used amongst the common people for destroying moths and cutaneous insects, and the infusion is given internally as a stoma-

chic and vermifuge.

MYRTUS CARYOPHYLLATA. The systematic name of the tree which affords the cassia bark. See Cassia caryophyllata.

MYRTUS COMMUNIS. Myrtus communis italica. The systematic name of the com-

mon myrtle. See Myrtus.

MYRTUS PYMENTA. The systematic name of the tree which bears the Jamaica pepper. Se *Pimento*.

MYSTAX. The hair which forms the beard in man, on each side the upper

lip.

MYURUS. An epithet for a sort of sinking pulse, when the second stroke is less than the first, the third than the second, &c. Of this there are two kinds: the first in when the pulse so sinks as not to rise again; the other, when it returns again, and rises in some degree. Both are esteemed bad presages.

Myxosancoma. (From μυξα, mucus, and σαςξ, flesh.) Mucocarnius. A tumour which is partly fleshy and partly mucous.

MYXTER. (From μυξα, the mucus of the nose.) The nose or nostril.

ated near the Red Sea, and is called by Mr. Bruce troglodite. Good myrrh is of a turbid black red colour, solid and heavy, of a peculiar smell, and bitter taste. medicinal effects are warm, corroborant, and antisceptic; it has been given as an emmenagogue in a dose from 5 to 20 grains; it is also given in cachexies, and applied externally as an antisceptic and vulnerary. In doses of half a drachm, Dr. Cullen remarks that it heats the stomach, produced sweat, and agreed with the balsams in affecting the urinary passages. It has lately come more into use as a tonic in hectical cases, and is said to prove less heating than most other medicines of that class. Myrrh dissolves almost totally in boiling water, but, as the liquor cools, the resinous matter Rectified spirit dissolves less of subsides. this concrete than water; but extracts more perfectly that part in which its bitterness, virtues and flavour reside; the resinous matter which water leaves undissolved is very bitter, but the gummy matter which spirit leaves undissolved is insipid, the spirituous solution containing all the ac-tive part of the myrrh: it is applied to ulcers, and other external affections of a putrid tendency; and also as a wash, when diluted, for the teeth and gums. There are several preparations of this drug in the London and Edinburgh pharmaco-

MYRRHINE. (From µngga, myrrh; so called because it smells like myrrh.)

Myrams. (From augga, myrrh; so named from its rnyrr-like smell) Sweet cicely; anti-scorbutic.

MYRINELEUM. (From μυρσινη, the myrtle, and λεαιον, oil.) Oil of myrtle.

MYRTACANTHA. (From μυρτος, a myrtle,

MYRTACANTHA. (From μυρτος, a myrtle, and αμανθα, a thorn; so called from its likeness to myrtle, and from its prickly leaves.) Butcher's broom. See Ruscus.

MYRTIDANUM. (From puggess, the myrtle.) An excrescence growing on the trunk of the myrtle, and used as an astringent.

MYNTILLUS. The berries which are directed in pharmacopæias by the name of bacca myrtillorum, are the fruit of the Vaccinium myrtillus of Linnæus. Prepared with vinegar they are esteemed as antiscorbutics, and when dry possess astringent virtues.

Myrtiform caruncles. See Glandulæ myrtiformes.

Myrtiform glands. See Glandula myrtiformes.

Myrtle, common. See Myrtus.

Myrtle, Dutch. See Myrtus brabantica.

## N.

N. In prescriptions this letter is a contraction for numero, in number.

NACTA. An abscess of the female breast

NADUCEM. A uterine coagulum, or mole.

Nævi matenni. Maculæ matrices. Stigmata. Metrocilides. Mother's marks. Marks on the skin of children, which are born with them, and which are produced by the longing of the mother for particular things, or her aversion to them; hence they resemble either mulberries, strawberries, grapes, pines, bacon, &c.

NAI CORONA. A name of the cowage.
NAIL. Unguis. A horny lamina, situ-

ated on the extremity of the fingers and toes.

NAKIR. According to Schenkius this means wandering pains of the limbs.

NAPELLUS. (A diminutive of napus, a kind of turnip; so called because it has a bulbous root like that of the napus.) See Aconitum.

NAPHÆ FLORES. Orange flowers are sometimes so called. See Aurantium.

NAPHTHA. Naφθa. A very fluid species of petroleum, of a lighter colour than petroleum, more or less transparent, perfectly thin and liquid, light, so as to float on water, odor ferous, volatile, and inflammable. It is found separated by nature from petroleum and blumen, but its separation is more readily effected by art. This fluid has been used for an external application for removing old pains, nervous disorders, such as cramps, contractions of the limbs, paralytic affections, &c.

. NAPIFOLIA. Bare cole.

NAPIUM. The name of the nipple wort. A species of lapsana. It is one of the bitter lactescent plants, similar in virtues to

endive. See Lapsana.

NAPUS. (From napus, Rabb.) Napus sulvestris. Bunias. Wild navew, or rape. The Brassica napus of Linnaus. The seeds yield upon expression a large quantity of oil called rape oil, which is sometimes ordered in stimulating liniments.

NAPUS DULCIS. See Rapus.

NARCISSIS The daffodil

NARCISSUS. The daffodil. A genus of plants in the Linnæan system. Class, Hexandria. Order, Monogynia.

NARCOSIS. (From vagaco, to stupefy.) Stupefaction, stupor, numbness.

NARCOTICS. (Narcotica, sc. Medicamenta. From yagraw, to stupefy.) Those

medicines which have the power of procuring sleep. See Anodynes.

Nard, Celtic. See Nardus Celtica. Nard, Indian. See Nardus Indica.

NARDOSTACHYS. (From ναςδω, spikenard, and ςαχω, sage.) A species of wild sage resembling spikenard in its leaves and smell.

NARDUS. (From nard, Sir.) Spikenard.

Nardus Celtica. Spica Celtic. Dioscoridis. Celtic nard. Valeriana Celtica of Linnæus. The root of this plant, a native of the Alps, has been recommended as a stomachic, carminative, and diuretic. At present it is only used in this country in the theriaca and mithridate, though its sensible qualities promise some considerable medicinal powers. It has a moderately strong smell, and a warm, bitterish, sub-acrid taste.

NARDUS INDICA. Spica nardi. Spica Indica. Indian nard or spikenard. The root of this plant, Andropogon nardus of Linnæus, is an ingredient in the mithridate and theriaca; it is moderately warm and pungent, accompanied with a flavour not disagreeable. It is said to be used by the Orientals as a spice.

NARDUS ITALICA. The lavendula latifolia.

NARDUS MONTANA. An old name of the

asarabacca.

Nandus Rustica. An old name of the

asarabacca. See Asarum.

(Pl. of naris.) Mycteres. The nostrils. The cavity of the nostrils is of a pyramidal figure, and is situated under the anterior part of the cranium, in the middle of the face. It is composed of fourteen bones, viz. the frontal, two maxillary, two nasal, two lachrymal, two inferior spongy, the sphænoid, the vomer, the ethmoid, and two palatine bones, which form several eminences and cavities. The eminences are the septum narium, the cavernous substance of the ethmoid bone, called the superior conchæ, and the inferior spongy bones. The cavities are three pair of pituitary sinuses, namely, the frontal, sphænoid and maxillary; the anterior and posterior foramina of the nostrils; the ductus nasalis, the sphæno-palatine foramina, and anterior palatine foramina. All these parts are covered with periosteum, and a pituitary membrane which secretes the mucus of the nostrils. The arteries of this cavity are branches of the internal maxillary. The veins empty themselves

into the internal jugulars. The nerves are branches of the olfactory, opthalmic, and superior maxillary. The use of the nostrils is for smelling, respiration, and speech.

NARIFUSORIA. (From nares, the nostrils, and fundo, to pour.) Medicines dropped

into the nostrils.

NARIS COMPRESSOR. See Compressor na-

NARTA. (Nagra, ex nardi odore, from its smell.) A plant used in ointments.

NARTHECIA. (From Narthecis, the island where it flourished.) Narthex. A kind of fennel.

NASALIA. the nose.) (From nasus, Errhines.

NASALIS LABIS SUPERIORI. See orbicu-

NASARIUM. (From nasus, the nose.) The mucus of the nose.

NASCALE. (From nasus, the nose.) wood or cotton pessary for the nose.

NASCAPTHUM. See Narcupthon.

See Depressor labii NASI, DEPRESSOR. superioris alæque nasi.

NASI OSSA. (nasus, the nose.) The two small bones of the nose that are so termed from the bridge of the nose. In figure they are quadrangular and oblong.

NASTURTIUM. (Quod nasum torquent, because the seed, when bruising, irritates the nose.) The name of a genus of plants in the Linnæan system. Class Tetradynamia. Order Siliquosa.

NASTURTIUM AQUATICUM. Laver odora-Cratevæ sium. Cressis. Cardamines. Water-cress. This indigenous plant Sysimbrium nasturtium of Linnaus; siliquis declinatis, foliis pinnatis, foliolis subcordatis, grows plentifully in brooks and stagnant waters. The leaves have a moderate pungent taste, emit a quick penetrating smell, like that of mustard seed, but much weaker. Water-cresses obtain a place in the materia medica, for their antiscorbutic qualities, which have been long very generally acknowledged by plysicians. The most pleasant way of administering them is in form of a salad.

NASTURTIUM HORTENSE. Dittander. This plant is the Lepidium satioum of Linnaus; floribus tetradynamiis; foliis oblongiis, multifidis; it possesses warm, nervine, and stimulating qualities, and is given as an antiscorbutic, antisceptic, and stomachic, espe-

cially by the lower order.

NASTURTIUM INDICUM. Acrivi-Flos sanguineus monardi. Nasturtium Peruvianum. Cardaminum minus. Greater Indian cress or nasturtium. Trapæolum majus of Linnaus. This plant is a native of Peru; it was first brought to France in 1684, and there called La grande capucine. In its recent state this plant, and more especially its flowers, have a smell and taste resembling those of water-cress; and the ed to Sicily and Italy.

leaves, on being bruised in a mortar, emit a pungent odour, somewhat like that of horse-radish. By distillation with water, they impregnate the fluid in a considerable degree with the smell and flavour of the plant. Hence the antiscorbutic character of the nasturtium seems to be well founded, at least as far as we are able to judge from its sensible qualities: therefore in all those cases, where the warm and antiscorbutic vegetables are recommended, this plant may be occasionally adopted as a pleasant and effectual variety. Patients, to whom the nauseous taste of scurvy-grass is intolerable, may find a grateful substitute in the nasturtium. The flowers are frequently used in salads, and the capsules are by many highly esteemed as a pickle. The flowers, in the warm summer months, about the time of sunset, have been observed to emit sparks like those of the electrical kind.

NATA. Natta. A species of wen with slender pendent neck. Linnæus speaks of it as rooted in a muscle.

NATES. (From nato, to flow: because the excrements are discharged from them.) 1. The buttocks, or the fleshy parts upon 2. Two of the eminences which we sit. of the tubercule quadragemina of the brain are so named, from their resemblance.

NATES CEREBRI. See Tubercula quadra-

gemina.

NATRON. (So called from Natron, a lake in Judea, where it was produced.) Natrum. 1. The name formerly given by the college of physicians to the alkali now called soda.

2. A native salt, which is found chrystallized in Egypt, in the lake called Natron, and in other hot countries, in sands surrounding lakes of salt water. It is an impure carbonate of soda.

3. The name of an impure carbonate of soda, obtained by burning Salsoli kali of Linnæus. Not only this, but various other plants, on being burned, are found to afford this alkali, and some in a greater

proportion than this: these are

The Salsola sativa, Lin. Salsola sonda. Lofling. Kali nispanicum supinum annuum sedi-feliis brevibus. Kali d'Alicante. This grows abundantly on that part of the Spa-nish coast which is washed by the Medi-terranean sea. This plant is deservedly first enumeratad by Professor Murray, as it supplies all the best soda consumed in Europe, which by us is called Spanish or Alicant soda, and by the Spanish merchants Barilla de Alicante. See Barilla.

Salsola soda, Lin. Kali majus cochleato This species, which Le salicor. grows on the French Mediterranean coast, is much used in Languedoc for the preparation of this salt, which is usually export-

Salsola tragus, Lin. affords an ordinary kind of soda, with which the French frequently mix that made in Languedoc. This adulteration is also practised by the Sicilians, who distinguish the plant by the term

Salicornia herbacca, Lin. is common in salt marshes, and on the sea-shore, all over Europe. Linnaus prefers the soda obtained from this plant to that of all the others; but though the quantity of alkali which it vields is very considerable, as a great portion of it is united with muriatic acid, it is mixed with much common salt.

Salicornia arabica, Lin. Mesembryanthemum nodiflorum, Lin. Plantago squarrosa, Lin. All these, according to Alpinus, afford this alkali. It has also been procured from several of the fuci, esphcially F. vesiculosus, and distinguished here by the name kelp. Various other marine plants might also be noticed as yielding an impure soda by combustion; but the principal are confined to the genus salsola, and that of salicornia. The salsola kali, on the authority of Rauwolf, is the species from which the salt is usually obtained in eastern countries.

It is to be regretted that the different kinds of soda, which are brought to European markets, have not been sufficiently analysed to enable us to ascertain with tolerable certainty the respective value of each; and indeed, while the practice of adulterating this salt continues, any attempts of this kind are likely to prove fruitless. The best information on this subject is to be had from Jessica, Mascorelle, Cadet, Borlare, and Sestini. In those places where the preparation of soda forms a considerable branch of commerce, as on the coast of the Mediterranean, seeds of the salsola are regularly sown in a proper situation near the sea, which usually shoot above ground in the course of a fortnight. About the time the seeds become ripe, the plants are pulled up by the roots, and exposed in a suitable place to dry, where their seeds are collected; this being done, the plants are tied up in bundles, and burned in an oven constructed for the purpose, where the ashes are then, while hot, continually stirred with long poles. The saline matter, on becoming cold, forms a hard solid mass, which is afterwards broken in pieces of a convenient size for exportation.

According to chymical analysis, the impure sodas of commerce generally contain a portion of vegetable alkali, and neutral salts, as muriate of soda and sulphate of potash, and not unfrequently some portion of iron is contained in the mass; they are therefore to be considered as more or less a compound, and their goodness to be estimated accordingly. The Spanish soda, of the best sort, is in dark coloured masses, of a bluish tinge, very ponderous, sonorous, dry to the touch, and externally abounding with small cavities, without any offensive smell, and very salt to the taste: if long exposed to the air, it undergoes a degree of spontaneous calcination. The best French soda is also dry, sonorous, brittle, and of a deep blue colour, approaching to black. The soda which is mixed with small stones, which gives out a fetid smell on solution. and is white, soft, and deliquescent, is of the worst kind. The method of purifying the impure carbonates of soda of commerce is directed in the London Pharmacopæia, under the article of Sodæ subcarbonas, and in the Edinburgh Pharmacopogia. under that of Sal alkalinus fixus fossilis purificatus. The pure crystals, thus formed of Alicant barilla, are colourless, transparent, lamcllated, of a rhomboidal figure; and one hundred parts arc found to contain twenty of alkali, sixteen of aërial acid, and sixty-four of water; but upon keeping the crystals for a length of time, if the air be not excluded, the water evaporates, and they assume the form of a white powder. According to Inslin, one ounce of water, at the temperature 62° of Fahr, dissolves five drachms and fifteen grains of the crystals.

NATRON MURIATUM. See Murias sode. NATRON PREPARATUM. See Subcarbonas

NATRON TARTARISATUM. See Tartarizata

NATRON VITRIOLATUM.

NATULE. (Dim. of nates, the buttocks; so called from their resemblance.) Two prominences of the brain. See Tubercula quadrigemina.

NATURAL ACTIONS. . Those actions by which the body is preserved; as hunger, thirst, &c. See Function.

NATURALIA. (From natura, nature.) The

parts of generation.

NAUSEA. (Naurea: from vaus, a ship; because it is a sensation similar to that which people experience upon sailing in a ship.) Nausiosis. Nautia. An inclination to vomit without effecting it; also a disgust of food, approaching to vomiting. It is an attendant on cardialgia, and a variety of other disorders, pregnancy, &c. occasioning an aversion for food, an increase of saliva, disgusted ideas at the sight of various objects, loss of appetite, debility, &c.

NAUSIOSIS. See Nausea.

NAUTIA. See Nausea.

NAUTICUS. (Nauticus, a sailor; so called from the use which sailors make of it, in climbing ropes.) A muscle of the leg, exerted in climbing up.

Navew, garden. See Rapus.

Navero, sweet. See Rapus. Navew, wild See Rapus. NAVICULARE OS. (F.

(From navicula, a little boat.) Naviformis. Navicularis. A bone of the carpus and Os scaphoides. tarsus is so called, from its supposed re- bugloss. semblance to a boat. See Carpus and Tar-

NAVICULATIS. See Naviculare os.

NAVIFORMIS. A name of the os navicu-

NEAPOLITANUS MORBUS. (From Neapolis, or Naples, because it was said to have been first discovered at Naples, when the French were in possession of it.) The venereal disease.

NEBULA. (From vegenn.) 1. A cloudy spot

in the cornea of the eye.

2. The cloud-like appearance in the urine, after it has been a little time at rest.

NECK. Collum. The parts which form the neck are divided into external and internal. The external parts are the common integuments, several muscles, eight pair of cervical nerves, the eighth pair of nerves of the cerebrum, and the great in-tercostal nerve; the two carotid arteries, the two external jugular veins, and the two internal; the glands of the neck, viz. the jugular, submaxillary, cervical, and thyroid. The internal parts are, the fauces, pharynx, œsophagus, larynx, and trachea. bones of the neck are the seven cervical vertebræ.

NECROSIS. (From vergow, to destroy.) This word, the strict meaning of which is only mortification, is, by the general con-sent of surgeons, confined to this affection of the bones. The death of parts of bones was not distinguished from caries, by the ancients. However, necrosis and caries are essentially different; for in the first, the part affected of the bone is deprived of the vital principle; but this is not the case when it is simply carious. Caries is very analogous to ulceration, while necrosis is exactly similar to mortification of the soft parts.

NECROSIS OSTILAGINEA. A painful convulsive contraction of the limbs.

NECTAR. NEUTAG. A wine made of honey.

NEDVIA. (From undue, the belly.) Nedus. The intestines.

Nunva. See Nedyia.

NEGBO CACHEXY. Cachexia Africana. Mal d'estomach of the French. A propensity for eating earth, peculiar to males as well as females, in the West Indies and Africa

NEIERA. (From runger, furthermost.) The

lower part of the belly

NEMOROSA. (From riemus, a grove; so called because it grows in woods.) A species of anemone,

Nep. See Nepeta.

NEPA THEOPHRASTI. The spartium sco-

NEPENTHES. (From vn neg. and wevbos, grief; so called from their exhilarating qualities.) A preparation of opium, and a kind of

NEPETA. (From nepte, Germ.) Herba felis. Nep, or catmint; so called because cats are very fond of it. The leaves of this plant, Nepata cataria of Linnæus:-floribus spicatis; verticillis subpedicellatis; foliis petiolatis, cordatis, dentata serratis, have a moderately pungent aromatic taste, and a strong smell, like an admixture of spearmint and penny royal. The herb is recommended in uterine disorders, dyspepsia, and flatulency.

NEPETA CATARIA. The systematic name

of the catmint. See Nepeta.

NEPETELLA. (Dim. of nepeta.) The lesser

NEPHELA. (Dim. of vepos, a cloud.) A cloudlike spot on the cornea of the eye.

NEPHELOIDES (From repean, a cloud, and esdos, a likeness.) Cloudy. Applied to the urine,

NEPHRALGIA. (From veogos, the kidney, and αλγος, pain.) Pain in the kid-

NEPHRALGIA CALCULOSA. Pain from stone

in the kidneys.

NEPHRALGIA RHEUMATICA. The lumbago,

or pain in the loins.

NEPHRELMINTUICA ISCHURIA. (From νεφεος, the kidney, and ελμίνς, a worm.) Applied to a suppression of urine from

Nephritic wood. See Lignum nephriticum. NEPHRITICA AQUA. Spirituous distillation

of nutineg and hawthorn flowers.

NEPHRITICS. (Nephritica, sc. medica-menta; from veogos, the kidney.) Medicines are so termed that are employed in the cure of diseases of the kidneys.

NEPHRITICUM LIGNUM. See Lignum ne-

phriticum.

NEPHRITIS. (From νεφερος, a kidney.)
Inflammation of the kidney. A genus of disease in the class pyrexie, and order phlegmasiæ, of Cullen; known by prexia, pain in the region of the kidneys, and shooting along the course of the ureter; drawing up of the testicles; numbness of the thigh; vomiting; urine high coloured, and frequently discharged; cos-Nephritis is tiveness, and colic pains. symptomatic of calculus, gout, &c.

This inflammation may be distinguished from the colic, by the pain being seated very far back, and by the difficulty of passing urme, which constantly attends it; and it may be distinguished from rheumatism, as in this the pain is but little influenced, or increased, either by motion or

pressure.

Nephritis is to be distinguished from a

calculus in the kidney, or ureter, by the symptoms of fever accompanying, or immediately following the attack of pain, and these continuing without any remarkable intermission; whereas, in a calculus of the kidney, or ureter, they do not occur until a considerable time after violent pain has been felt. In the latter case, too, a numbness of the thigh, and a retraction of the testicle on the affected side, usually takes place.

The causes which give rise to nephritis are, external contusions, strains of the back, acrids conveyed to the kidneys in the course of the circulation, violent and severe exercise, either in riding or walking, calculous concretions lodged in the kidneys, or ureters, and exposures to cold. In some habits, there is an evident predisposition to this complaint, particularly the gouty, and in these there are often translations of the matter to the kidneys, which very much

imitate nephritis.

An inflammation of the kidney is attended with a sharp pain on the affected side, extending along the course of the ureter; and there is a frequent desire to make water, with much difficulty in making it; the body is costive, the skin is dry and hot, the patient feels great uneasiness when he endeavours to walk, or sit upright; he lies with most ease on the affected side, and is generally troubled with nausea and frequent vomiting.

When the disease is protracted beyond the seventh or eighth day, and the patient feels an obtuse pain in the part, has frequent returns of chilliness and shiverings, there is reason to apprehend that matter is forming in the kidney, and that a suppura-

tion will ensue.

Dissections of nephritis shew the usual effects of inflammation on the kidney; and they likewise often discover the formation of abscesses, which have destroyed its whole substance. In a few instances, the kidney has been found in a scirrhous state.

NEPHROLITICA ISCHURIA. (From 140905, a kidney, and 21605, a stone.) Applied to an ischury, from a stone in the kid-

neys.

NEPHROMETRE. The psox muscles.

NEPHROPLETHORICUS. (From νεωζος, a kidney, and πληθωζα, a plethora.) Applied to a suppression of urine from a plethora.

Nephrophers Mariers, (From 1499%, a kidney, and φλεγμα, phlegm.) Applied to a suppression of urine from pituitous or mu-

cous matter in the kidneys.

NEPHROPLEGICUS. (From νεφρος, a kidney, and πληγη, a stroke.) A suppression of urine from a paralysis of the kidney is called ischuria nephroplegica.

NEPHROPYICUS. (From veogos, a kidney, and woor, pus.) Applied to a sup-

pression of urine from purulent matter in the kidneys.

NEPHROS. (From νιω, to flow, and φιζω, to bear; as conveying the urinary fluid.) A kidney.

NEPHROSPASTICUS. (From νεφξος, a kidney, and σπαφ, to contract.) Applied to a suppression of urine from a spasm of the kidneys.

NEPHROTHRYMBOIDES. (From vegges, a kidney, and bgopker, a grumous concretion, and bdoc, a likeness.) Applied to a suppression of urine from grumous bloud in the

kidneys.

NEPHROTOMY. Nephrotomia; from νεφερε, a kidney, and τεμνω, to cut.) The operation of extracting a stone from the kidney. A proceeding which, perhaps, has never been actually put in practice. The cutting into the kidney, the deep situation of this viscus, and the want of symptoms by which the lodgment of a stone in it can be certainly discovered, will always be strong objections to the practice.

NERIUM. (From pages, humid; so called because it grows in moist places.) The name of a genus of plants in the Linnaan system. Class, Pentandria. Order,

Monogynia.

NERIUM ANTIDYSENTERIUM. The systematic name of the tree which affords the Cadoga pala bark. See Conissi cortex.

NEROLI OLEUM. Essential oil of orange

flowers. See Aurantium.

NERVALIA OSSA. (From nervus, a nerve.) The bones through which the nerves

pass. NERVE. Nervus. Formerly it meant a sinew. This accounts for the opposite meanings of the word nervous; which sometimes means strong, sinewy; snd sometimes weak, and irritable. Nerves are long, white, medullary cords, that serve They originate from the for sensation. brain and spinal marrow; hence they are distinguished into cerebral and spinal nerves, and distributed upon the organs of sense, the viscera, vessels, muscles, and every part that is endowed with sensibility. The cerebral nerves are the olfactory, optic, motores oculorum, pathetici, or trochleatores, trigimini, or divisi, abducent, auditory, or acoustic, par vagum and lingual. Heister has drawn up the uses of these nerves in the two following verses:

Olfaciens, cernens, oculosque movens pa-

tiensque,

Gustans, abducens, audiensque, vagansque, loquensque.

The spinal nerves are thirty pair, and are divided into eight pair of cervical, twelve pair of dorsal, five pair of lumber, and five of sacral nerves. In the course of the nerves there are a number of knots: these are called ganglions; they are commonly of an oblong shape, and of a grayish colour,

somewhat inclining to red, which is, perhaps, owing to their being extremely vascular. Some writers have considered these little ganglions as so many little brains. Lancisi faneied he had discovered muscular fibres in them, but they certainly are not of an irritable nature. A late writer (Dr. Johnson) imagines they are intended to deprive us of the power of the will over certain parts, as the heart, for instance; but if this hypothesis were well founded, they should be met with only in nerves leading to voluntary muscles; whereas it is certain that the voluntary muscles receive nerves through ganglions. Dr. Munro, from observing the accurate intermixture of the minute nerves which compose them, considers them as new sources of nervous The nerves, like the blood-vessels, in their course through the body, communicate with each other, and each of these communications constitute what is called a plexus, from whence branches are again detached to different parts of the body. The use of the nerves is to convey the principles of motion and sensibility to the brain, from all parts of the system, and from the brain to every part of the system. The manner in which this operation is effected is not yet determined. The inquiry has been a constant source of hypothesis in all ages, and has produced some ingenious ideas, and many erroneous positions, but without having hitherto afforded much satisfactory information. Some physiologists have considered a trunk of nerves as a solid cord, capable of being divided into an infinite number of filaments, by means of which the impressions of feeling arc conveyed to the common sensorium. Others have supposed each fibril to be a canal, carrying a volatile fluid, which they term the uervous fluid. Those who contend for their being solid bodies are of opinion that feeling is occasioned by vibration; so that, for instance, according to this hypothesis, by pricking the finger, a vibration would be occasioned in the nerve distributed through its substance; and the effects of this vibration, when extended to the sensorium, would be an excital of pain; but the inelasticity, the softness, the connection, and the situation of the nerves, are so many proofs that vibration has no share in the eause of feeling.

A Tuble of the Nerves. CEREBRAL NERVES.

- 1. The first pair, called olfactory.
- 2. The second pair, or optic nerves. 3. The third pair, or oculorum motorii.
- 4. The fourth pair, or pathetici.
  5. The fifth pair, or trigemini, which gives off
  - a. The ophthalmic, or orbital nerve, which sends
    - 1. A branch to unite with one from the

- sixth pair, and form the great intercostal nerve.
- 2. The frontal nerve.
- 3. The luchrymal.
- 4 The wasul.
- b. The superior maxillary, which divides
  - 1. The spheno palatine nerve.
  - 2. The posterior alveolar.
    3. The infra orbital.
- e. The inferior maxillary nerve, from which arise
  - 1. The internal lingual.
  - 2. The inferior maxillary, properly so
- 6. The sixth pair, or abducentes, which send off
  - 1. A branch to unite with one from the fifth, and form the great inter-
- 7. The seventh pair, or auditory nerves, these arise by two separate beginnings,
  - The portio dura, a nerve going to the
  - The portio mollis, which is distributed
  - on the ear. The partio dura, or facial nerve, gives off the chorda tympani, and then
- proceeds to the face 8. The eighth pair, or par vagum, arise from the medulla oblongata, and join with the accessory of Willis. The par vagum
  - 1. The right and left recurrent nerve.
  - 2. Several branches in the chest, to form the cardiac plexus.
  - 3. Several branches to form the pulmonic plexus.
  - 4. Several branches to form the asophagcal plexus.
  - 5. It then forms in the abdomen the stomuchic plexus.
  - 6. The hepatic plexus.
  - 7. The splenic plexus.
  - 8. The renal plexus, receiving several branches from the great intercostal, which assists in their formation.
- 9. The ninth pair, or lingual nerves, which go from the medullar oblongata to the tongue.

SPINAL NERVES.

Those nerves are called spinal, which pass out through the lateral or intervertibral foramina of the spine.

They are divided into cervical, dorsal, lumbar, and sacral nerves

CERVICAL NERVES.

The cervical nerves are eight pairs.

The first are called the occipital; they arise from the beginning of the spinal marrow, pass out between the margin of the occipital foramen and atlas, form a ganglion on its transverse process, and are distributed about the occiput and neck.

The second pair of cervical nerves send a

NERVE.

branch to the accessory nerve of Willis, and proceed to the parotid gland and ex-

ternal ear.

The third cervical pair supply the integuments of the scapula, cucullaris, and triangularis muscles, and send a branch to form with others the diaphragmatic nerve.

The fourth, fifth, sixth, seventh, and eighth pair all converge to form the brachial plexus, from which arise the six following

NERVES OF THE UPPER EXTREMITIES. 1. The axillary nerve, which sometimes arises from the radial nerve. It runs backwards and outwards around the neck of the humerus, and ramifies in the muscles of the scapula.

2. The external cutaneal, which perforates the coraco-brachialis muscle, to the bend of the arm, where it accompanies the median vein as far as the thumb, and is lost

in its integuments.

3. The internal cutaneal, which descends on the inside of the arm, where it bifurcates. From the bend of the arm the anterior branch accompanies the basilic vein, to be inserted into the skin of the palm of the hand; the posterior branch runs down the internal part of the fore-arm, to vanish in

the skin of the little finger.

4. The median nerve, which accompanies the brachial artery to the cubit, then passes between the brachialis internus, pronator rotundus, and the perforatus and perforans, under the ligament of the wrist to the palm of the hand, where it sends off branches in every direction to the muscles of the hand, and then supplies the digital nerves, which go to the extremities of the

thumb, fore and middle fingers.

5. The ulnar nerve, which descends between the brachial artery and basilic vein, between the internal condyle of the humerus and the olecranon, and divides in the fore-arm into an internal and external The former passes over the ligament of the wrist and sesamoid bone, to the hand, where it divides into three branches, two of which go to the ring and little finger, and the third forms an arch towards the thumb, in the palm of the hand, and is lost in the contiguous muscles. The latter passes over the tendon of the extensor carpi ulnaris and back of the hand, to supply also the two last fingers.

6. The radial nerve, which sometimes gives off the axillary nerve. It passes backwards, about the os humeri, descends on the outside of the arm, between the brachialis externus and internus muscles to the cubit; then proceeds between the supinator longus and brevis, to the superior extremity of the radius, giving off various branches to adjacent muscles. place it divides into two branches; one goes along the radius, between the supinator longus and radialis internus to the back of the hand, and terminates in the interosseous muscles, the thumb and three first fingers; the other passes between the supinator brevis and head of the radius, and is lost in the muscles of the fore-arm.

DORSAL NERVES.

The dorsal nerves are twelve pairs in num-The first pair gives off a branch to the brachial plexus. All the dorsal nerves are distributed to the muscles of the back, intercostals, serrati, pectoral, abdominal muscles, and diaphragm. The five inferior pairs go to the cartilages of the ribs, and are called costal

LUMBAR NERVES.

The five pair of lumbar nerves are bestowed about the loins and muscles, skin of the abdomen and loins, scrotum, ovaria, and diaphragm. The second, third, and fifth pair unite and form the obturator nerve, which descends over the psoas muscle into the pelvis, and passes through the foramen thyroideum to the obturator muscle, tri-

ceps, pectineus, &c.

The third and fourth, with some branches of the second pair, form the crural nerve, which passes under Poupart's ligament with the femoral artery, sends off branches to the adjacent parts, and descends in the direction of the sartorius muscle to the internal condyle of the femur, from whence it accompanies the saphena vein to the internal ankle, to be lost in the skin of the great

The fifth pair are joined to the first pair of the sacral nerves.

SACRAL NERVES.

There are five pair of sacral nerves, all of which arise from the cauda equina, or termination of the medulla spinalis, so called from the nerves resembling the tail of a horse. The four first pair give off branches to the pelvic viscera, and are afterwards united to the last lumbar, to form a large plexus, which gives off

The ischiatic nerve, the largest in the The ischiatic nerve, immediately at its origin, sends off branches to the bladder, rectum, and parts of generation; proceeds from the cavity of the pelvis through the ischiatic notch, between the tuberosity of

the ischium and great trochanter, to the ham, where it is called the popliteal nerve. In the ham it divides into two branches. 1. The peroneal, which descends on the

fibula, and distributes many branches to the muscles of the leg and back of the

2. The tibial, which penetrates the gastrocnemii muscles to the internal ankle, passes through a notch in the os calcis to the sole of the foot, where it divides into an internal and external plantar nerve, which supply the muscles and aponeurosis of the foot and the toes.

Physiology of the Nervous System.

The nervous system, as the organ of sense and motion, is connected with so many functions of the animal economy, that the study of it must be of the utmost importance, and a fundamental part of the study of the whole economy. The nervous system consists of the medullary substance of the brain, cerebellum, medulla oblongata, and spinalis; and of the same substance continued into the nerves, by which it is distributed to many different parts of the body. The whole of this system seems to be properly distinguished into these four parts.

1. The medullary sub-tance contained in the cranium and vertebral cavity; the whole of which seems to consist of distinct fibres, but without the smaller fibres being separated from each other by any evident en-

veloping membranes.

2. Connected with one part or other of this substance are, the nerves, in which the same medullary substance is continued; but here more evidently divided into fibres, each of which is separated from the others by an enveloping membrane, derived from

the pia mater.

3. Parts of the extremities of certain nerves, in which the incdullary substance is divested of the enveloping membranes from the pia mater, and so situated as to be exposed to the action of certain external bodies, and perhaps so framed as to be affected by the action of certain bodies only: these are named the sentient extremities of the nerves.

4. Certain extremities of the nerves, so framed as to be capable of a peculiar contractility; and, in consequence of their situation and attachments, to be, by their contraction, capable of moving most of the solid and fluid parts of the body. These are named the moving extremities of the nerves: they are commonly named moving,

or muscular fibres.

These several parts of the nervous system are every where the same continuous medullary substance which is supposed to be the vital solid of animals, so constituted in living animals, and in living systems only, as to admit of motions being readily propagated from any one part to every other part of the nervous system, so long as the continuity and natural living state of the medullary substance remains. In the living man, there is an immaterial thinking substance, or mind, constantly present, and every phenomenon of thinking is to be considered as an affection or faculty of the mind alone. But this immaterial and thinking part of man is so connected with the material and corporeal part of him, and particularly with the nervous system, that motions excited in this give occasion to thought, and thought, however occasioned, gives occasion to new motions in the nervous system. This mu-

tual communication, or influence, is assumed with confidence as a fact: but the mode of it we do not understand, nor pretend to explain; and therefore are not bound to obviate the difficulties that attend any of the suppositions which have been made concerning it. The phenomena of the nervous system occur commonly in the following order. The impulse of external bodies acts upon the sentient extremities of the nerves; and this gives occasion to perception, or thought, which, as first arising in the mind, is termed sensation. sensation, according to its various modification, gives occasion to volition, or the willing of certain ends to be obtained by the motion of certain parts of the body; and this volition gives cccasion to the contraction of muscular fibres, by which the motion of the part required is produced. As the impulse of bodies on the sentient extremities of a nerve does not occasion any sensation, unless the nerve between the sentient extremity and the brain be free; and as, in like manner, volition does not produce any contraction of muscles, unless the nerve between the brain and muscle be also free, it is concluded, from both these facts, that sensation and volition, so far as they are connected with corporeal motions, are functions of the brain alone; and it is presumed, that sensation arises only in consequence of external impulse producing motion in the sentient extremities of the nerves, and of that motion's being thence propagated along the nerves to the brain; and, in like manner, that the will operating in the brain only, by a motion begun there, and propagated along the nerves, produces the contraction of muscles. From what is now said, we perceive more distinctly the different functions of the several parts of the nervous system, as distinguished in, 1. The sentient extremities seem to be particularly fitted to receive the impressions of external bodies: and, according to the difference of these impressions, and of the condition of the scntient extremity itself, to propagate along the nerves motions of a determined kind, which, communicated to the brain, give occasion to sensation. 2. The brain seems to be a part fitted for, and susceptible of, those motions, with which sensation, and the whole consequent operations of thought, are connected: and thereby is fitted to form a communication between the motions excited in the sentient, and those in consequence arising in the moving extremities of the nerves, which are often remote and distant from each other. 3. The moving extremities are so framed as to be capable of contraction, and of having this contraction excited by motion propagated from the brain, and communicated to the contractile fibre. 4. The nerves, more strictly so called, are to

NEU

be considered as a collection of medullary fibres, each enveloped in its proper membrane, and thereby so separated from every other, as hardly to admit of any communication of motion from any one to the others, and to admit only of motion along the continuous medullary substance of the same fibre, from its origin to the extremities, or contrarywise. From this view of the parts of the nervous system, of their several functions and communication with each other, it appears, that the beginning of motion in the animal economy is generally connected with sensation: and that the ultimate effects of such motion are chiefly actions depending immediately upon the contraction of moving fibres, between which and the sentient extremities the communication is by means of the brain.

NERVEA SPONGIOSA. The cavernous

part of the penis.

NERVI INTERCOSTALES INNOMINATI. The

fish pair of nerves.

NERVINES. (Nervina, sc. medicamenta, from nervus.) Neurotics. Medicines that relieve disorders of the nerves. They are all the antispasmodics, and the various pre-parations of bark and iron.

NERVORUM RESOLUTIO. A species of

apoplexy or palsy.

NERVOSUM OS. The occipital bone. Nervous consumption. See Atrophia. Nervous diseases. See Neuroses. Nervous Fever. See Febris nervosa. Nervous head ache. See Cephalalgia.

NERVOUS FLUID. Nervous principle. The vascularity of the cortical part of the brain, and of the nerves themselves, their softness, pulpiness, and natural humid appearance, give reason to believe that between the medullary particles of which they are principally composed, a fine fluid is constantly secreted, which may be fitted to receive and transmit, even more readily than other fluids do, all impressions which are made on it. It appears to exhale from the extremities of the nerves. The lassitude and debility of muscles from too great exercise, and the dulness of the sensorial organs from excessive use, would seem to prove this It has no smell nor taste; for the cerebrine medulla is insipid and inodo-Nor has it any colour, for the cerebrum and nerves are white. It is of so subtile a consistence, as never to have been detected. Its mobility is stupendous, for in less than a moment, with the consent of the mind, it is conveyed from the cerebrum to the muscles, like the electric matter. Whether the nervous fluid be carried from the organ of sense in the sensorial nerves to the cerebrum, and from thence in the motory nerves to the muscles, cannot be positively affirmed, but may be proved The constitu ent principles of this liquid are perfectly unknown, as they cannot be rendered visible by art, or proved by experiment. Upon

making a ligature upon a nerve, the motion of the fluid is interrupted, which proves that something corporeal flows through it. It is therefore a weak argument to deny its existence because we cannot see it; for who has seen the matter of heat, oxygen, azot, and other elementary bodies, the existence of which no physician in the prc-The electric matter, sent day doubts? whose action on the nerves is very great, does not appear to constitute the nervous fluid: for nerves exhibit no signs of spontaneous electricity; nor can it be the magnetic matter, as the experiment of Gavian with the magnet demonstrates; nor is it oxygen, nor hydrogen, nor azot; for the first very much irritates the nerves, and the other two suspend their action. The nervous fluid, therefore, is an element sui generis, which exists and is produced in the nerves only; hence, like other elements, it is a thing unknown, and only to be known by its effects. The pulpous softness of some nerves, and their lax situation, does not allow them and the brain to act on the body and soul only by oscillation. Lastly, a tense chord, although tied, oscillates. The use of the nervous fluid is, 1. It appears to be an intermediate substance between the body and the soul, by means of which the latter thinks, perceives, and moves the muscles subservient to the will. Hence the body acts upon the soul, and the soul upon the body. 2. It appears to differ from the vital principle; for parts live and are irritable which want nerves, as bones, tendons, plants, and insects.

NESTIS. (From vn, neg. and ετθιω, to eat; so called because it is generally found

empty.) The jejunum.

Nettle, common. See Urtica. Nettle, dead. See Lamium album. Nettle-rash. See Urticaria.

NEUROCHONDRODES. (From veugev, a sinew, and xovogos, a cartilage.) A hard substance between a sinew and a cartilage.

NEUROLOGY. (From veugov, a nerve, and Asyos, a discourse.) The doctrine of the nerves.

NEUROMETORES. (From veugov, a nerve, and merga, a matrix.) The psoas muscles are so called by Fallopius, as being the re-

pository of so many small nerves.

NEUROSES. (From veuger, a nerve.) Nervous diseases. The second class of Cullen's nosology is so called; it comprehends affections of sense and motion, disturbed; without either idiopathic pyrexia, or topical diseases.

(From veuger, a nerve.) NEUROTICA.

Nervous medicines.

NEUROTOMY. (Neurotomia, from veugev, a nerve, and τεμνω, to cut.) A dissection of the nerves. Also a puncture of a nerve.

NEUTRAL SALTS. Secondary salts. Under the name of neutral or secondary ralts are comprehended such matters as are composed of two primitive saline substances combined together. They are called neutral, because they do not possess the characters of acid nor alkaline salts, which are primitive salts; such are Epsom salts, alum, nitre, &c.

NEXUS. (From necto, wind.) A complication of substances in one part, as the membrane which involves the fœtus.

NICKEL. It is to Cronstedt that we are indebted for the discovery of this metal; though the substance from which he extracted it was known in the year 1694. Cronstedt proved it to be a peculiar metal Nickel is found in nain the year 1751. ture generally in the metallic state, more rarely in that of an oxyd. Its ores have a coppery red colour, generally covered more or less with a greenish grey efflorescence. The most abundant ore is that termed sulphuret of nickel, or kupfernickel, which is a compound of nickel, arsenic, sulphuret of iron, and sometimes cobalt and copper. This ore occurs either massive, or disseminated, but never crystallized; it is of a copper colour, sometimes yellowish, white, or grey. It exists also combined with oxvgen, and a little carbonic acid, in what is called native oxyd of nickel, (nickel ochre;) it then has an carthy appearance, and is very friable; it is found coating kupfernickel, and seems to originate from the decomposition of this ore. It is found contaminated with iron in the mineral substance called martial nickel; this native combination, when fresh broken, has a lamellated texture; when exposed to the air, it soon turns black, and sometimes exhibits thin rhomboidal plates placed irregularly over each other. It is also found united to arsenic, cobalt, and alumine in the ore, called arseniate of nickel.

Properties.-Nickel, when free from heterogeneous substances, is of a pale flesh colour When fresh broken it has a strong lustre. It has a fine-grained com-pact texture, and can be a little flattened by hammering, similar to cast iron. leaves a trace when rubbed upon the polished surface of a hard stone. Its specific gravity is 7.380. It requires a very in-tense heat for fusion. When exposed for a long time to a humid atmosphere, its surface becomes gradually covered with an oxyd of a greenish hue; this takes place likewise and more rapidly, when heated in contact with air. When fused with borax it produces a glass of a hyacinth colour. It unites with phosphorus by fusion, and forms with it a phosphuret which is very fusible, white, and in brilliant needles. With sulpher it forms, by fusion, a hard vellow mass, with small brilliant facets, Sulphuric acid, assisted by heat, dissolves Nitric acid acts on it more readily. Muriatic acid, when heated on it, likewise

dissolves part of it. Boracic and phosphoric acids seem to have little or no action on nickel. It readily unites with gold, and renders that metal white and brittle likewise fuses with platina, silver, and bismuth. It does not alloy with mercury. It is easily oxydated by the nitrate and the super-oxygenated muriate of potash. It is not magnetic, nor has it the smallest effect upon the magnetic needle. This has been proved by Mr. Chenevix, who has also shown that the magnetism of common nickel is owing to the iron which so obstinately adheres to it. For a portion of iron, so small as not to be detected by the best chemical tests, when combined with nickel. is capable of communicating magnetic properties to the whole mass as strong as if the whole were composed of steel.

Method of obtaining Nickel.—To obtain nickel, the ore is first roasted, in order to free it from sulphur and arsenic; it is then changed into a greenish oxyd. This oxyd is mixed with two or three parts of black flux. The mixture is put into a crucible, and, being covered with decripitated muritate of soda, it is brought to the state of fusion, by the strongest heat of a smith's forge.

When the crucible is broken, there is found at the bottom, under brown, blackish, and sometimes blue scoria, a button of a yellowish white colour, equal in weight to a tenth, a fifth, and even a half, of the ore employed. This metal, however, is still far from being pure.

In order to purify it, the button obtained. is again broken into small pieces, strongly heated, and then digested with its own weight of concentrated sulphuric acid, and distilled to dryncss. The dry mass is dissolved in water, and filtered. This solution, in general, deposits crystals of arsenic, and finally affords da k green crystals of sul-phate of nickel. This sulphate is re-dis-solved in water, and decomposed by carbonate of potash. The precipitate is dis-solved in liquid ammonia; the blue solution leaves a residuum, which is filtered off, and the filtered solution saturated with nitric acid. The nuckel is then precipitated in the form of a grevish green powder, by carbonate of potash. From this oxyd the metallic nickel is obtainable by exposing it to incat, when made into a mass with oil and a little charcoal powder.

The nickel obtained in this manner was, until lately, considered as perfectly pure. It possesses, however, magnetic properties. It is therefore contaminated with iron.

In order to obtain this metal in a state of absolute purity, the following method of Chevenix must be had recourse to:

Take the native sulphuret of nickel, reduce it to powder, and roast it in contact with charcoal powder over a gentle fire. When no more fumes arise, pour thea nitric acid over it, and dissolve it by heat in

a Florence flask. Decant the solution, filter it through bibulous paper, and evaporate it to dryness in a glass basin. Dissolve the nitrate of nickel in a sufficient quantity of distilled water, and decompose it by the addition of the strongest liquid ammonia, taking care to add it in The oxyd of nickel and cobalt will thus be re-dissolved; then let the solution stand undisturbed till a precipitate again ensues. The solution must then be evaporated; it becomes blue during this process, by the precipitation of the co-balt, which should be separated, and the evaporation be then continued to dryness; the residue will be pure oxyd of nickel.

In order to reduce this oxyd to the metallic state, let it be made into a paste with oil, mix it with about three parts of black flux, and put it into a crucible, covering it with borax and muriate of soda, and heat the crucible violently for an hour and a half in a forge, a button will then be ob-

tained, which is pure nickel.

NICOPHORUS. (From vikin, victory, and φερω, to bear, so called because victors

were crowned with it )

NICOTIANA. (From Mr. Nicott, who first brought it into Europe.) 1. The name of a genus of plants in the Linnzan system. Class Pentandria. Order Monogy-ufa. 2. The pharmacopæial name of the officinal tobacco. Petum, by the Indians, Hyosciamus Peruvianus. Tabacum. celt. The Virginia tobacco. Nicotiana tabacum of Linnæus :- foliis lanceolato-ovatis sessilibus decurrentibus florentibus acutis, is the plant employed medicinally. It is a very active narcotic and sternutatory. A decoction of the leaves is much esteemed in some diseases of the skin, and is by some said to be a specific against the itch. The fumes and the decoction are employed in obstinate constipations of the bowels, and very frequently with success; it is necessary, however, to caution the practitioner against an effect mostly produced by its exhibition, namely, syncope, with cold sweats; and in some instances death.

NICOTIANA AMERICANA. American or

Virginian tobacco. See Nicotiana.

Tobacco Anglicum. NICOTIANA MINOR. Priapeia. Hyosciamus luteus. English tobacco. This plant, Nicotiana rustica of Linnæus, is much weaker than the Virginian tobacco, the leaves are chiefly used to smoke vermin, though they promise, from their more gentle operation, to be a safer remedy in some cases than the former.

The systematic NICOTIANA RUSTICA. name of the English tobacco. See Nico-

tiana minor.

NICOTIANA TABACUM. The systematic name of the tobacco-plant. See Nicoti-

(Quasi nigrella, from NIGELLAS.

niger, black, so named from its black seed.) 1. The name of a genus of plants in the Linnæan system. Class, Polyandria. Order, Pentagynia. 2. The pharmaco-poial name of the Nigella satira of Linnæus. Devil in a bush, or fennel-flower. It was formerly employed medicinally as an expectorant and deobstruent, but is now deservedly fallen into disuse.

NIGELLA SATIVA. The systematic name of the devil in a bush. See Ni-

(From Nigella, fen-NIGELLASTRUM. nel-flower.) Pscudomelanthium. Lychnis segetum major. Gethago. Nigella offici-Lychnoides segetum. narum. Cockle, a herb resembling the nigella

Night-blindness. See Nyctalopia.

NIGHT-MARE. Incubus. nia gravans. The nervous or indisposed persons are oppressed during sleep with a heavy pressing sensation on the chest, by which respiration is impeded, or the circulation of blood intercepted, to such a degree as to threaten suffocation. Frightful ideas are recollected on waking, which occupied the dreaming mind. Frequent attempts are made to cry out, but often without effect, and the horrors and agitations felt by the patient are inexpressibly frightful. The sensations generally originate in a large quantity of wind, or indigestible matter in the stomach of suppereaters, which, pressing the stomach against the diaphragm, impede respiration, or render it short and convulsed. Inflated intestines may likewise produce similar effects, or mental perturbations.

There is another species of night-mare mentioned by authors, which has a more dangerous tendency; and this arises from an impeded circulation of blood in the lungs, when lying down, or too great re-laxation of the heart and its impelling Epilepsy, apoplexy, or sudden powers. death, are sometimes amongst the consequences of this species of disturbed sleep. Polypi in the large vessels, aneurisms, water in the thorax, pericardium, or lungs, empyema, &c. are amongst the most dangerous causes. See Oncirodynia.

Nightshade, American. See Phytolacca

decandria.

Nightshade, deadly. See Belladonna. Nightshade, garden. See Solanum. Nightshade, Palestine. See Solanum

Nightshade, woody See Dulcamara.

NIGHITIES. (From niger, black.) A caries is called nigrities ossium, a blackness of the bone.

NIHILUM ALBUM. A name formerly given to the flowers, or oxyd of zinc.

'NINSI RADIX. Ninzin. Nindsin. root was long supposed to be the same as ginseng. It now appears, however, to be the produce of a different plant, the siun minsi of Linnaus, foliis serratis, pinnatis; ramis ternatis, possessing similar though weaker properties than ginseng.

NINZIN. See Ninsi radix.

NIPPLE. The small projecting portion in the middle of the breasts of men and women. It is much larger in the latter, and has an opening in it, the exeretory ducts of the lacteal glands.

Nipple-wort. Sce Lampsana.

NITRAS. (From nitrum, nitre.) nitrate; a salt formed by the union of the nitric acid and a different bases, as the nitrate of potash, soda, silver, &c.

NITRAS AMMONIE. Alkali volatile nitratum. Sal ammoniacus nitrosus. Ammonia nitrata. A salt composed of the acid of nitre and ammonia, the virtues of which are irritating, diuretie, and deobstrucnt; externally, it is resolvent and sialagogue.

NITRAS ARGENTI. Causticum lunare. Argentum nitratum. "Take of silver an ounce, nitric acid, a fluid-ounce and a half, distilled water, two fluid-ounces." Mix the nitric acid and water, and dissolve the silver therein on a sand bath; then inerease the heat gradually, that the nitrate of silver may be dried Melt the salt in a crueible over a slow fire until, the water being evaporated, it shall cease to boil; then pour it quickly into moulds of convenient shape. Its virtues are corrosive and astringent. Internally it is exhibited in very small quantities, in epilepsy; and externally it is employed to destroy fungous exerescences, callous ulcers, fistulas, &c. In the latter disease it is employed as an injection: from two grains to three being dissolved in an ounce of distilled water.

NITRAS POTASSÆ. See Nitre.

NITRAS POTASSE FUSUS. Sal prunclla. Aitrum tabulatum. This salt, besides the nitric acid and potash, contains a little sulphurie acid.

Alkali minerale nitra-NITRAS SODE. tum. Nitrum cubicum. Its virtues are similar to those of nitrate of potash, for which it may be safely substituted.

Nitrate of potash. Sec Nitre. Nitrate of silver. Sec Nitras argenti. NITRE, vilgov. Nitrum. Potassæ nitras. Salpetræ. Aldurat. Algali. Atac. Baurack. Acusto. Halinitrum. Salt petre. A perfeet neutral salt, formed by the union of the nitrous acid with the vegetable alkali. Its taste is cooling, and it does not alter the colour of the syrup of violets. Nitre exists in large quantities in the earth, and is continually formed in inhabited places; it is found in great quantities upon walls which are sheltered from the rain. It is of great use in the arts; it is the principal ingredient in gunpowder; and, burned with different proportions of tartar, forms the substances called fluxes. It is of considerable importance in medicine, as a febrifuge, diuretic, and antiphlogistic remedy.

NITRIC ACID. Acidum nitrieum. The London College direct this acid to be made by distilling equal parts, by weight, of dried nitrate of potash and sulphuric acid, two pounds of each. Mix them in a glass retort, then distil the nitric acid in a sand bath, until a red vapour arises; lastly, having added to the acid first distilled an ounce more of dry nitrate of potash, distil the nitric acid again in a similar

The specific gravity of nitrie acid is to that of water, as 1 600 to 1,000. An ounce diluted with water ought to dissolve of a lump of lime-stone immersed therein seven

drachms.

This acid undiluted is a powerful caustic, and is sometimes employed as such by surgeons to destroy fungous excrescencies. Very much diluted it is exhibited internally as a tonic and antisceptic, in the cure of typhoid fevers, scurvy, syphiloid diseases, and other cachexies.

Nitric-oxyd of mercury. See Nitrico-oxydum hydrargyri.

NITRICO-OXYDUM HYDRARGYRI. Hydrargirus nitratus ruber. Mercurius corrosivus ruber. Mercurius præcipitatus corrosivus. Nitrie-oxyd of mercury. Red precipitate. "Take of purified mercury, by weight, three pounds :- of nitrie acid, by weight, a pound and a half:—of distilled water, two pints." Mix in a glass vessel, and boil the mixture in a sand bath, until the mercury being dissolved, the water also evaporated, and a white mass remain. Rub this into powder, and put it into another shallow vessel, then apply a moderate heat, and raise the fire gradually until the red vapour shall cease to rise." This preparation is very extensively employed by surgeons as a stimulant and escharotic, but its extraordinary activity does not allow of its being given internally. Finely levigated and inixed with common cerates, it is an excellent application to indolent ulcers, especially those which remain after burns and scalds, and those in which the granulations are indolent and flabby. It is also an excellent caustie application to chancres.

NITROGEN. (From vilgov, nitre, and gropeas, to generate; so called because it is the generator of nitre.) Azote. Alkaligen. A simple body, very abundant in nature, though not producible alone, or in an insulated state. It is not distinctly perceptible to the human senses, however aided by instruments. We know it only in its combination. But the reality of its existence is unquestionable; since we can mark its passage out of one combination into another: since we know the laws of chemical attraction to which it is subject; since we discern the precise character of those simple substances with which it is combinable, and can distinguish the nature of the new compounds which the combination pro-

duces. The separate existence and fieculiar nature of this substance were first discovered by Dr. Rutherford. It is the radical principle of our atmospheric air, and other gazeous substances, and forms a constituent part of animal and vegetable sub-It is a component part of the nitric acid, and of ammonia. It proba-bly enters into the formation of alkalies, and it may be considered as a real alcaligen or alkalizing principle, in opposition to oxygen, which, as we have noticed be-fore, is the principle of acidity. One of the most remarkable combinations, into which nitrogen is known to enter, is that which takes place between it and light and caloric. The compound thus produced is called

NITROGEN GAS.

Phlogisticated air. Azotic gas. Mephitic air. Mofette.

Properties .- Nitrogen gas, or azotic gas, as it is also called, is not possessed of any remarkable property capable of characterizing it; but is principally distinguished by certain negative qualities, namely, it is extremely hurtful to respiration, and quickly kills animals. Plants thrive and even flourish in it. It has no sensible taste. It neither reddens blue vegetable colours, nor precipitates lime, or barytic water. Its weight is to common air, as .985. to 1.000 No combustible substance burns in nitrogen gas; but it is capable of combustion in combination with oxygen gas, when exposed to the action of the electric spark. It is not absorbable by water. It is capable of dissolving sulphur, phosphorus and charcoal, in minute quantities. It unites to hydrogen under certain conditions, and constitutes with it ammonia. When united to oxygen in different proportions, it produces atmospheric air, gazeous oxyd of azote or nitrogen, nitrous gas, nitrous acid and nitric acid. It is a component part of all animal substances, and communicates to them their most distinctive characters. was discovered by Dr. Rutherford of Edin-

Nitrogen gas has been found by Priestley in the Bath waters, and by Dr. Pearson in

the Buxton waters.

Methods of obtaining Autrogen Gas .-Nitrogen gas may be obtained by various means. For instance, it has been long since ascertained that air, which has served the purposes of combustion and respiration, is no longer proper for these uses. Chymists have availed themselves of this circumstance, in order to obtain nitrogen gas in the following manner.

1 Make a quantity of sulphuret of potash or sulphuret of iron into a paste with water, and place the mixture in a saucer or plate over water, on a stand raised above the fluid; then invert over it a jar or bellglass, and allow this to stand for a day or The air contained in the bell glass will gradually diminish, as will appear from the ascent of the water, until only about three-fourths of its original bulk remain.

When no further diminution takes place, the vessel containing the sulphuret must be removed, and the remaining air will be

found to be nitrogen gas.

In this experiment the moistened sulphuret of potash has a great affinity to oxygen. it attracts and separates it from the atmospheric air, and the nitrogen gas is left behind; the sulphur is, during the experiment, converted into sulphuric acid, which unites to the alkali and forms sulphate of potash. The water with which the sulphuret is moistened likewise undergoes a decomposition, as shall be more fully proved in an-

other place.

2. Nitrogen gas may likewise be obtained from fresh animal substances. this purpose cut a piece of lean muscular flesh into small pieces, introduce them into a retort, and pour over them weak nitric acid. If the heat of a lamp not exceeding 80° Fahr. be then gently applied, the gas will be speedily obtained; for all animal substances are composed of nitrogen, carbon, hydrogen, and oxygen; and on adding nitric acid in this way, the equilibrium of the respective affinities is destroyed, the nitrogen gas becoming separated.

That the nitric acid does not furnish the nitrogen gas is obvious, from its saturating after its action as large a quantity of alkali as before, consequently it could not have

suffered any alteration

The fibrous part of animal matter is that which affords the most nitrogen gas; next to this all the concretive parts, such as the clot of blood; next to that, albuminous matter, such as the serum and the white of eggs; gelatinous substances afford the least

3. Nitrogen gas may likewise be obtained, by causing oxygenated muriatic acid gas to be received in a vessel containing liquid ammonia, for ammonia consists of livdrogen and nitrogen. The hidrogen of the ammonia unites to the oxygen of the oxygenated muriatic acid, and forms water, heat is evolved, the nitrogen becomes free, and the oxygenated muriatic acid becomes converted into simple muriatic acid.

Nitrogen gaz. See Azot. NITROGEN, GAZEOUS OXYD OF. This combination of nitrogen and oxygenwas formerly called the dephlogisticated nitrous gaz, but now gazeous oxyd of nitrogen, or nitrous oxyd. It was first discovered by Priestley. Its nature and properties have since been investigated (though not very accurately) by a society of Dutch chymists.

Professor Davy has examined with uncommon accuracy the formation and properties of all the substances concerned in its production. He has detected the sources of error in the experiments of Priestley and the Dutch chemists, and to him we are indebted for a thorough knowledge of this gas. We shall therefore exhibit the philosophy of this gazeous fluid as we find it in his researches concerning the nitrous oxid.

Properties —It exists in the form of permanent gas. A candle burns with a brilliant flame and crackling noise in it; before its extinction the white inner flame becomes surrounded with a blue one. Phosphorus introduced into it, in a state of actual inflammation, burns with in-creased splendour, as in oxygen gas. Sulphur introduced into it, when burning with a feeble blue flame is instantly extinguished; but when in a state of vivid inflammation, it burns with a rose-coloured flame. Ignited chareoal burns in it more brilliantly than in atmospheric air. Iron wire, with a small piece of wood affixed to it, when inflamed, and introduced into a vessel filled with this gas, burns vehemently, and throws out bright scintillating sparks. No combustible body however burns in it, unless it be previously brought to a state of vivid inflammation. sulphur may be melted, and even sublimed in it, phosphorus may be liquified in it without undergoing combustion. Nitrous oxid is pretty rapidly absorbed by water that has been boiled; a quantity of gas equal to rather more than half the bulk of the water may be thus made to disappear, the water acquires a sweetish taste, but its other properties do not differ perceptibly from common water. The whole of the gas may be expelled again by heat. does not change blue vegetable colours. has a distinctly sweet taste, and a faint but agreeable odour. It undergoes no diminution when mingled with oxigen or nitrous gas. Most of the liquid inflammable bodies, such as ether, alcohol, volatile and fat oils, absorb it rapidly and in great quantity. Acids exert but little action on it. The affinity of the neutro-saline solutions for gazeous oxid of nitragen is very feeble. Green muriate and green sulpliate of iron, whether holding nitrous gas in solution, or not, do not act upon it None of the gases when mingled with it, suffer any perceptible change at common temperatures; the muriatic and sulphurous acid gases excepted, which undergo a slight expansion. Alkalies freed from carbonic acid, exposed in the dry or solid form, have no action upon it; they may however be made to combine with it in the nascent state, and then constitute saline compounds of a peculiar nature. These combinations deflagrate when heated with charcoal, and are decomposed by acids; the gazeous exid of nitragen being disengaged. It undergoes

no change whatever from the simple effect of light. The action of the electric spark, for a long while continued, converts it into a gas, analogous to atmospherie air and nitrous acid! the same is the case when it is made to pass through an ignited earthen tube. It explodes with hydrogen in a variety of proportions, at very high temperatures; for instance, when electric sparks are mide to pass through the mixture. Sulphureted, heavy and light carbonated hydrogen gases, and gazeous oxid of carbon likewise burn with it when a strong red heat is applied. 100 parts by weight of nitrous oxid, contain 36.7 of oxigen and 63.3 of nitrogen; 100 cubic inches weigh 50 grains at 55° temperature and 30 atmospherie pressure. Animals, when wholly confined in gazeous oxid of nitrogen, give no signs of uneasiness for some moments, but they soon become restless and then die. When gazeous oxid of nitrogen is mingled with atmospherie air, and then received into the lungs, it generates highly pleasurable sensations; the effects it produces on the animal system are eminently distinguished from every other elemical agent. It excites every fibre to action, and rouses the faculties of the mind, inducing a state of great exhiliration, an irresistible propensity to laughter, a rapid flow of vivid ideas, and unusual vigour and fitness for muscular exertions, in some respects resembling those attendant on the pleasantest period of intoxication, without any subsequent languor, depression of the nervous energy, or disagreeble feelings; but more generally followed by vigour, and a pleasurable disposition to exertion, which gradually subsides.

Such are the properties that characterize

the nitrous oxid.

The Dutch chemists and some French and German philosophers assert that it cannot be respired; that burning phosphorus, sulphur, and charcoal are extinguished in it, &c. It is probable they did not examine it in a state of purity, for it is otherwise difficult to account for these and many other erroneous opinions.

Methods of obtaining gazeous oxid of nitrogen.—Gazeous oxid of nitrogen is produced, when substances, having a strong affinity with oxigen are brought into contact with nitric acid, or with nitrous gas. It may therefore be obtained by various processes, in which nitrous gas or nitric acid is decomposed by substances capable of attracting the greater part of their oxigen. The most commodaus and expeditious as well as cheapest mode of obtaining it, is by decomposing nitrate of annuonia, at a certain temperature, in the following manner:—

1. Introduce into a glass retort some pure nitrate of ammonia, and apply the heat of an Argand's lamp, the sait will

3 Z \*

soon liquefy, and, when it begins to boil, gas will be evolved. Increase the heat gradually till the body and neck of the retort become filled with a semi-transparent milky-white vapour. In this state the temperature of the fused nitrate is between 340° and 480°. After the decomposition has proceeded for a few minutes, so that the gas evolved quickly enlarges the flame of a taper held near the orifice of the retort, it may be collected over water, care being taken during the whole process, never to suffer the temperature of the fused nitrate to rise above 500° Fahr. which may easily be judged of, from the density of the vapours in the retort, and from the quiet ebulhtion of the fused nitrate; for if the heat be increased beyond this point, the vapours in the retort acquire a reddish and more transparent appearance; and the fused nitrate begins to rise, and occupy twice the bulk it did before. The nitrous oxid, after its generation, is allowed to stand over water, for at least six hours, and is then fit for respiration or other experiments.

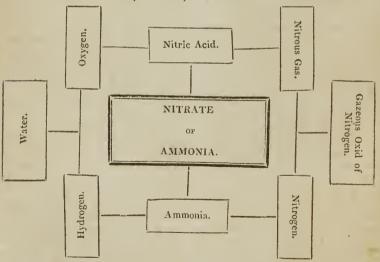

Explanation.—Nitrate of ammonia consists of nitric acid and ammonia; nitric

acid is composed of nitrous gas and oxigen; and ammonia consists of hydrogen and nitrogen. At a temperature of about 480° the attractions of hydrogen for nitrogen in ammonia, and that of nitrous gas for oxigen in nitric acid, are diminished; while, on the contrary, the attractions of the hydrogen of ammonia for the oxigen of the nitric acid, and that of the remaining nitrogen of the ammonia for the nitrous gas of the nitric acid, are increased; hence all the former affinities are broken, and new ones produced, namely, the hydrogen of the ammonia attracts the oxigen of the nitric acid, the result of which is water; the nitrogen of the ammonia combines with the liberated nitrous gas, and forms nitrous oxid. The water and nitrous oxid produced, probably exist in binary combination in the aëriform state, at the temperature of the decomposition.

Such is the philosophy of the production of gazeous oxid of nitrogen, by decomposing nitrate of ammonia at that temperature, given by Davy.

To illustrate this complicated play of affinity more fully, the following sketch may not be deemed superfluous.

A Diagram exhibiting the production of Gazeous Oxid of Nitrogen by decomposing Nitrate of Ammonia, at 480° Fahr.

Professor Davy has likewise pointed out, that, when the heat employed for decomposing nitrate of ammonia is raised above the before-stated temperature, another play of affinities takes place, the attractions of nitrogen and hydrogen for each other, and of oxigen for nitrous gas, are still more diminished, whilst that of ni-

trogen for nitrous gas is totally destroyed, and that of hydrogen for oxigen increased to a greater extent. A new attraction likewise takes place, namely, that of nitrous gas for nitric acid to form nitrous varour, and a new arrangement of principles is rapidly produced: the nitrogen of the ammonia having no affinity for any of the

single principles at this temperature, enters into no binary compound; the oxigen of the nitric acid forms water with the hydrogen, and the nitrous gas combines with the nitric acid to form nitrous vapour.

All these substances most probably exist in combination, at the temperature of their production; and at a lower temperature assume the form of nitrous acid, nitrous gas, nitrogen, and vater; and hence we see the necessity of not heating the nitrate of animonia above the before-stated temperature.

On account of the rapid absorption of gazeous oxid of nitrogen by water, it is economical to preserve the fluid which has been used to confine this gas, and to make use of it for collecting other quantities of it. In order to hasten its production, the nitrate of ammonia may be previously freed from its water of crystallization by gently fusing it in a glass or Wedgewood's basin for a few minutes, and then keeping it for use in a well-stopped bottle.

2. Nitrous oxid may likewise be obtained by exposing common nitrous gas to alkaline sulphites, particularly to sulphite of potash containing its full quantity of water of crystallization. The nitrous oxid produced from nitrous gas by sulphite of potash has all the properties of that generated from the decomposition of nitrate of

The conversion of nitrous gas into nitrous oxid by these bodies, depends on the abstraction of a portion of its oxigen by the greater affinity of the sulphite presented to it. The nitrogen and remaining oxigen assume a more condensed state of existence, and constitute nitrous oxid.

3. Nitrous oxid may also be obtained by mingling together nitrous gas and sulphurated hydrogen gas. The volume of gases in this case is diminished, sulphur deposited, ammonia, water, and nitrous oxid are formed.

The change of principles which takes place in this experiment depends upon the combination of the hydrogen of the sulphurated hydrogen gas, with different portions of the oxigen and nitrogen of the nitrous gas, to form water and ammonia, and to deposit sulphur. The remaining oxigen and nitrogen being left in due proportion constitute nitrous oxid.

Remark.—This singular exertion of attraction by a simple body appears highly improbable a priori; but the formation of animonia, and the non-oxigenation of the sulphur, clucidate the fact. In performing this experiment care should be taken that the gases should be rendered as dry as possible; for the presence of water considerably retards the decomposition.

4. Nitrous oxid may also be produced by presenting alkaline sulphurets to nitrous

gas. Davy observed that a solution of sulphuret of strontia, or barytes, answers this purpose best.

This decomposition of nitrous gas is not spelly produced by the abstraction of oxigen from the nitrous gas, to form sulphuric acid. It depends equally on the decomposition of the sulphurated hydrogen dissolved in the solution or liberated from it. In this process sulphur is deposited and sulphuric acid formed.

5. Nitrous oxid is obtained in many circumstances similar to these in which nitrous gas is produced. Dr. Priestley found that nitrous oxid was evolved, together with nitrous gas, during the solution of iron, tin, and zinc in nitrous acid.

It is difficult to ascertain the exact rationale of these processes, for very complicated agencies of affinities take place. Either the nascent hydrogen arising from the decomposition of the water by the metallic substance may combine with portions of the oxigen and nitrogen of the nitrous gas, and thus by forming water and ainmonia, convert into nitrous oxid; or the metallic substance may attract at the same time oxigen from the water and nitrous gas, whilst the nascent hydrogen of the water seizes upon a portion of the nitrogen of the nitrous gas, to form ammonia. The analogy between this process and the decomposition of nitrous gas by sulphurated hydrogen, render the first opinion most probable.

Such are the principal methods of obtaining nitrous oxid. There are no reasons, Davy thinks, for supposing that nitrous oxid is formed in any of the processes of nature, and the nice equilibrium of affinity by which it is constituted forbids us to hope for the power of composing it from its simple principles. We must be content to produce it artificially.

NITRO-MURIATIC ACID. The compound acid formed by uniting the nitrous and marine acids. It is commonly known by the name of aqua regia. See Oxigenated muriatic acid.

Nitrous acid. See Acidum nitrosum.

NITROUS GAS. The name of nitrous gas is given to an aëriform fluid, consisting of a certain quantity of nitrogen gas and oxigen. It is an elastic, colon less fluid, having no sensible taste; it is neither acid nor alkaline; it is exceedingly hurtful to animals, producing instant suffocation, whenever they attempt to breathe it. The greater number of combustible bodies refuse to burn it. It is nevertheless capable of supporting the combustion of some of these bodies. Phosphorus burns in nitrous gas when introduced into it in a state of inflammation; pyrophorus takes fire in it spontaneously.

It is not decomposable by water, though 100 cubic inches of this fluid, when freed from air, absorb about 11.8 cubic inches of gas. This solution is void of taste; it does not redden blue vegetable colours; the gas is expelled again when the water is made to boil or suffered to freeze. It has no action on nitrogen gas even when assisted by heat. It is decomposed by several metals at high temperatures

Its specific gravity, when perfectly pure, is to that of atmospheric air as 1 093 to 1.

Ardent spirit, saccharine matters, hydrocarbonates, sulphureous acid and phosphorus have no action on it. It is not sensibly changed by the action of light. Heat dilates it. It rapidly combines with oxigen gas at common temperatures, and converts it into nitrous acid. Atmospheric air produces the same effect but with less intensity. It is absorbable by green sulphate, muriate and nitrate of iron, and decomposable by alkaline, terrene, and metallic sulphurets, and other bodies that have a strong affinity for oxigen; but it is not capable of combining with them chemically, so as to form salme compounds the greatest number of bodies which absorb it, it may be again expelled by the application of heat.

It communicates to flame a greenish colour before extinguishing it; when mixed with hydrogen gas it acquires the property of burning with a green flame. It is absorbable by nitric acid and renders it

fuming.

When exposed to the action of caloric in an ignited porcelain tube, it experiences no alteration, but when electric sparks are made to pass through it, it is decomposed and converted into nitrous acid, and nitrogen gas. Phosphorus does not sline in it. It is composed of 56 parts of oxigen and

44 nitrogen.

Methods of obtaining nitrous gas .-1. Put into a small proof, or retort, some copper wire or pieces of the same metal, and pour on it nitric acid of commerce diluted with water, an effervescence takes place and nitrous gas will be produced. After having suffered the gas to escape for a few minutes on account of the atmospheric air contained in the retort, collect the gas in the water-apparatus as usual. order to obtain the gas in a pure state, it must then be shook for some time in contact with water. The water in this instance suffers no alteration, on the contrary, the acid undergoes a partial decomposition; the metal robs the nitric acid of the greatest part of its oxigen and becomes oxidated; the remainder of the acid having lost so much of its oxigen, becomes thereby so altered, that at the usual temperature it can exist no longer in the liquid state, but instantly expands and assumes the form of gas; ceasing at the same time to act as an acid, and exhibiting different properties.

Instead of presenting copper to nitrie acid, iron, zinc, mercury, or silver may be made use of. The metals best suited for the production of nitrous gas are silver, mercury, and copper.

2. Nitrous gas may likewise be obtained by synthesis. This method of obtaining it we owe to Dr. Milner of Cambridge.

Into the middle of an earthen tube about 20 inches long and three-fourth wide, open at both ends, put as much coarsely-powdered manganese as is sufficient acarly to lill it. Let this tube traverse a furnace having two openings opposite to each other. To one end of the tube lute a retort containing water strongly impregnated with ammonia, and to the other adapt a bent glass tube which passes into the pneumatic trough. Let a fire be kindled in the furnace, and when the manganese may be supposed to be red-hot, apply a gentle heat to the retort and drive over it the vapour of the ammonia; the consequence will be that nitrous gas will be dclivered at one end of the tube, at the time that the ammonia enters the other end; and this effect does not take place without the presence of the alkali.

Explanation.—Ammonia consists of hydrogen and nitrogen, its hydrogen combines with the oxigen which is given out by the ignited manganese, and forms water, its nitrogen unites at the same time to another portion of the oxigen, and constitutes the

nitrous gas.

There is a cause of deception in this experiment, against which the operator ought to be on his guard, lest he should conclude no nitrous gas is formed, when in reality there is a considerable quantity. ammonia, notwithstanding every precaution, will frequently pass over undecomposed. If the receiver in the pneumatic trough is filled with water, great part of this will indeed be presently absorbed; but still some portion of it will mix with the nitrous gas formed in the process. Upon admitting the atmospheric air, the nitrous gas will become decomposed, and the red nitrous fumes instantly unite with the alkali. The receiver is presently filled with white clouds of nitrate of ammonia: and in this manner a wrong conclusion may easily be drawn from the want of the orange colour of the nitrous fumes. A considerable quantity of nitrous gas may have been formed, and yet no orange colour appear, owing to this circumstance; and therefore it is easy to understand how small a quantity of nitrous gas may be most effectually disguised by the same

Dr. Milner also obtained nitrous gas, by passing ammoniacal gas over sulphate of iron deprived of its water of crystallization Water impregnated with this gas forms NITROUS ACID.

The common mode of obtaining nitrous acid is to decompose nitrate of potash by means of sulphuric acid with the assistance of heat. The nitrie acid suffers a partial decomposition during the pro-cess, and hence it is the nitrous acid which is obtained in the first process of dis-

It seems to be true that nitrous acid of a much darker orange red colour is obtained by decomposing nitrate of potash by means of sulphate of iron, than when the same salt is decomposed by sulphuric acid. The following is the process made use of

by our manufacturers.

Take a quantity of sulphate of iron, deprived of its water of crystallization by heat, and mix it with an equal weight of dry nitrate of potash; put the mixture into a glass retort, to which a very spacious receiver has been luted, containing a little water, and begin the distillation with a very slow fire. As soon as the red vapours cease to come over, let the fire be slackened, and when the vessels are cooled, the receiver may be cautiously withdrawn, and its contents quickly transferred through a glass funnel iuto a bottle, furnished with a ground stopper.

NITROUS OXID. See Nitrogen, gazeous

oxid of.

NITRUM. See Natron and nitre.

NITRUM PURIFICATUM. See Nitre.

NITRUM VITRIOLATUM. Sulphuric acid and soda. See Sulphate of soda.

Noullis. (Quase noscibilis, from nosco, to know.) The heart, by way of eminence, is called nobilis valvula, the noble

Noule METALS. A name formerly bestowed on the perfect metals, gold, silver,

and platina.

NOCTAMBULATIO. (From nox, night, and ambulo, to walk.) Noctisurguim. Walking in the night, when asleep. See Oneiro-

NOCTISURGUIM. See Noctambulatio.

Nocturnal emissions. See Gonorrhaa dormientium.

Nonning onicus. The systematic name of this plant is Cnicus cernuus of Linnaus. In Siberia the tender stalks are first peeled and then boiled and eaten by the inhabit-

NODE. Nodus. A hard circumscribed tumour, proceeding from a bone, and caused by a swelling of the periosteum; they appear on every part of the body, but are more common on such as are thinly covered with muscles, as the os frontis, forepart of the tibia, radius and ulna. As they inerease in size they become more painful

from the distention they oceasion in the periosteum. When they continue long the bone becomes completely earous.

Norus. (From Anad, to tie, Heb.) A node or swelling upon a bone. See

NOLI ME TANGERE. A species of herpes affecting the skin and cartilages of the nose, very difficult to cure, because it is exasperated by most applications. disease generally commences with small, superficial spreading ulcerations on the alæ of the nose, which become more or less concealed beneath furfuraceous scabs. The whole nose is frequently destroyed by the progressive ravages of this peculiar disorder, which sometimes cannot be stopped or retarded by any treatment, external or internal.

NOMÆ. (From yepo, to eat.) Noma. Ulcers that sometimes attack the cheek or vulva of young girls. They appear in the form of red and somewhat livid spots; are not attended with pyrexia, pain, or tumour, and in a few days become gangre-

nous.

NON-NATURALS. Under this term, ancient physicians comprehend air, meat and drink, sleep and watching, motion and rest, the retentions and excretions, and the affections of the mind; or, in other words, those principal matters which do not enter into the composition of the body, but at the same time are necessary to its existence.

Nonus. (Quasi novenus, from novem, nine.) Humeri musculus placentini. The ninth or coracoid muscle of the shoulder.

NOPAL. Nopalnochetzth. The plant that

feeds the cochineal insect.

NORLANDICE BACCE. The fruit of the rubus arcticus of Linnæus, which this illustrious character found very grateful and refreshing in his tour through the northern part of Sweden. In putrid fever, exanthematous diseases, and scurvy, they promise to be, like other summer fruits, very serviceable.

NOSE. Nasus. See Nares.

Nose, bleeding of. See Epistaxis.

Nosocomium. (From vovos, a disease, and xomen, to take care of.) Nosodychium. An hospital.

Nosobochium. See Nosocomium.

NOSOLOGY. (Nosologia, from voros, a disease, and xoyos, a discourse.) The doctrine of the names of diseases. Modern physicians understand by nosology the arrangement of diseases in classes, genera, species, &c. The following are the approved arrangements of the several nosologists. That of Dr. Cullen is generally adopted in this country, and next to it the arrangement of Sauvage.

ORDER I. GENERAL. 173 Eclampsia 177 Anchylogossum 169. Colica meconialis 174. Atrophia 178 Annigo 170 ---- lactentium 173. Rachitis. 179 Purpura 171 Dearthea infantum ORDER H. LOCAL. 180. Crusta lactea. 176. Imperforation 172. Aphthæ

NOSTALGIA. (Nosanzia: from vosew, to return, and axyos, pain.) A vehement desire for r visiting one's country. A genus of disease in the class Locales, and order Dysorexiæ of Callen, known by impatience when absent from one's native home, and a vehement desire to return, attended with gloom and melancholy, loss or appetite, and want of sleep.

Normus. (From votos, spurious.) 1. Those ribs which are not attached to the sternum are called not a costa, the spurious ribs.

2. The term is applied to such diseases as resemble others; as peripoeumonia nothu, &c.

Notleus (From vorov, the back.) An epithet of the spinal macrow.

Normones. (From vorte, moisture.) plied to a fever, attended with a vi ia on of the fluids, or a colliquative wasting.

NOUFER'S MEDICINE. This famous remedy was invented by Madam Noufer, as a cure for the tape-worm See Filix

NUH CULA. (Dim. of nubes, a cloud.) A cloud in the urine. A white speck in the eye.

Nuces GALLE. Common gulls. NICES PURGANTES. See Ricimes. Nucreta. See Nun moschata.

The hand part or mape of the NUCHA. neck.

The nutmeg NUCISTA.

NUCLEUS ('E nuce, trom the ant.) A kernel. A fruit cuclosed in a hard shell

Bacc.e bermuden-NUCCLE SAPONARIE. ses. Soup b rres. Bermudas berries. spherical fruit, about the size of a cherry, whose cortical part is yellow, glossy, and so transparent as to shew the sphericle black nut which ratties with n, and which includes a block kernel. It is the produce of the Sapindus saponaria of Linnaus. The

cortical part has a bitter taste, and no smell; it raises a soapy froth with water, and has similar effects with soap in washing, and it is said to be a medicine of singular and specific virtue in chlorosis.

NUMMULAHIA. (From nummus, money; so called because its leaves are round and of the size of he old silver two-pence.) Hirundinaria. Centimorbia. Moneywort. This plant, Lysimachia nummularia of Linnaus, is very common in our ditches. It was formerly accounted vulnerary; it possesses antiscorbu ic and restringent qualities. Boerhaave looks upon it as simil. rato a mixture of scurvy-grass with sorrel.

NUT, COUOA. The fruit of the Cocos nucifera of Lonnaus Within the not is found a kernel, as pleasant as an almond, and also a large quantity of siquor resembling milk, which the Indians greedily drink before the fruit is ripe, it being then pleasant, but when the nut is majured, the liquor becomes sour. Some full-grown nuts will contain a pint or more of this milk, the frequent drinking of which seems to have no bad effects upon the Indians; vet Europeans should be cautious of making too free with it at first, f r when Lionel Wafer was at a small island in the South Sea, where the tree grew in plenty, some of his men were so delighted with it, that at parting they ocre resolved to drink the r fill, which they did; but their appetites had like to have cost them their lives, for though they were not drink, yet they w re so chilled and be unabed, that hey could not stand, and were obliged to be carried abourd by those who had more prudence than themselves, and it was many days before they recovired. shells of these nuts being hard, and capable of receiving a polish, they are often cut transversely, when, being mounted on stands, and having their edges silvered, or gilt, or otherwise ornamented, they serve the purpose of draiking-cups. The leaves of the tree are used for thatching, for brooms, baskets, and other utquisls; and of the reticular web, growing at their base, the Indian women make cauls and aprons.

NUTRITION. Nutritio. Nutrition may be considered the completion of the assimilating functions. The food changed by a series of decompositions, animalized and rendered similar to the being which it is designed to nourish, applies itself to those organs, the loss of which it is to supply; and this identification of nutritive matter to our organs constitutes nutrition.

The living body is continually losing its constituent parts, which a variety of causes are incessantly carrying off; several of its organs are constantly engaged in separating humours which pass off loaded with a part of its substance, consumed by the uniting action of air and caloric; internal friction,

agitated by a pulsatory motion, detaches

Thus the animal machine is continually destroyed, and at distant periods of life does not contain a single particle of the same constituent parts. An experiment made with madder, (rubia tinctorum,) which, when mixed with the food, reddens the bones of animals, proves in a very decisive manner this perpetual decomposition of living animal matter. Entirely to obliterate the diffused red colour of bones, it is only necessary to suspend for a time the use of this root. Therefore, if the most compact and solid parts be in a continual motion of decomposition and recomposition, there can be no doubt but that this motion must be more rapid in those parts, the constituent principles of which are in the smallest degree of cohesion, as in fluids.

It has been an object of consideration to determine the period of the entire renovation of the body; it has been said that an interval of seven years was necessary for the same particles to be totally obliterated, and their place supplied by others; but this change should seem to be more rapid in infancy and youth; it should also seem to be retarded in manhood, and require a very long time to be accomplished in old age, when all our parts acquire a remarkable degree of con istence and fixity, at the same time that the vital actions become more languid. There is no doubt but that sex, temperature, climate, profession, mode of living, and a variety of other causes, accelerate and retard this period.

so that it is impossible to affirm any thing certain on the precise time of its duration.

In proportion as our parts are destroyed, they are renewed by homogeneous particles, or such as are exactly similar to themselves; otherwise their nature, which is always alike, would suffer continual changes. When the nutritive matter has been animal zed, or arsimilated to the body which it is designed to nourish, by the organs of digestion, absorption, circulation, respiration, and secretion, the parts which it supplies retain and incorporate it with their own substance. This nutritive identification is variously effected in different parts, as the brain, muscles, bones. &c : each of these appropriates to itself, by a true secretion, that which is found analogous to its nature, and rejects the heterogeneous particles brought by different vessels, chiefly by the arteries. A bone is a secretory organ, that becomes incrusted with phosphat of lime; the lymphatic vessels, which in the work of nutrition perform the office of excretory ducts, remove this salt after it has remained a certain time in the areolæ of its texture. It is the same in muscles with respect to the fibrin, and in the brain with albumen, each part im-bibes, and renders solid in its structure, such juices as are of the same nature, in consequence of a power, of which the affinity of aggregation of the chymists gives us an idea, and perhaps furnishes us with an exact model.

A part to acquire nourishment should possess sensibility and motion; a ligature placed on its arteries and nerves, by destroying both these faculties, prevents it from being nourished, or having life. The blood flowing in the veins, and the fluid of the absorbents, contain vivilying and reparatory parts, in much smaller quantity than arterial blood; it is even generally believed that lymph and venous blood do not contain any thing directly nutritious.

The mechanism of nutrition would be explained after having precisely deter-mined the differences of composition that exists between the aliments on which we exist and the exact substance of our organs, if we could distinguish how each function divests them of their characters, to invest them with our properties for each individual part, to co-operate in changing their nutritious principle into our own peculiar structure. To resolve this problem, let us suppose a man living entirely on vegetables, which, in fact, constitute the principal part of the subsistence of the generality of men; whatever portion of the plant he may consume, whether stalk, leaves, flowers, seeds, or roots; carbon, hydrogen, and oxygen enter their composition, which may be always, by a strict analysis, resolved into water and carbonic acid; to these three constituent principles,

sometimes a small quantity of azot, salts, and other things, is united. If we then examine the nature of the organs of this man, whose diet consists exclusively in vegetables, they will be proved of a composition very different from the kind of food; azot predominates, although the vegetable substance contain it in very small quantity, and many new products will be discovered which had not been distinguirhed in the aliment, but which abound in the body receiving nourishe ent, and seem produced by the act of nutrition.

The essential part of this function, therefore, is to cause the nutri ive matter to pass into a more advanced state of composition, to deprive it of a portion of its carbon and hydrogen, to give a predominance of azot, and develop several substances which were not before distinguishable. Every living body, without except on, seems to possess a faculty of forming and decomposing substances, by the assistance of which it is supported, and of giving rise to new products. The marine-plant, the ashes of which form soda, if sown in a box filled with earth that does not contain a particle of that alkah, and moistened with distilled water, furnishes it in as great a quantity as if the plant had been growing on the borders of the sea, in a swampy soil, always inundated by brackish or salt water.

Living bodies are the proper elaboratories in which such combinations and decompositions occur as art cannot imitate; bodies that to us appear sample, as soda and silex seem to form themselves of other parts, while some bodies, the composition of which we cannot determine, as certain metals suffer inevitable decompositions: from which we may fairly conclude, that the powers of nature in the composition and decomposition of bodies, far surpass the science of chymists. For a substance to be employed in our nourishment, it should be capable of change and fermentation, that is, susceptible of experiencing an internal and spontaneous motion, by which its clements change their combination and qualities. This condition of spontaneous mutability, excludes from the class of aliment every thing which is not organized, or constituted part of a living being : thus minerals are absolutely refractory to the action of our organs, which cannot convert them into their own peculiar substance. The common principle dra'n from alimentary substances, however vari-ous they may be, called by Hippocrates the aliment, is probably a composition capalile of a great degree of change and fermentation; this is also the opinion of all those who have endeavoured to discover Lorry thinks it is a mucous rts nature. body; Cullen considers it saccharine;

Hallé believes it to be an hydro-carbonated oxyd, which only differs from the oxalic acid by having a smaller portion of oxygen. It is obvious that these three sentiments have the greatest resemblance, since oxygen, carbon, and hydrogen, united in different proportions, form a mucus, a sac-charine body, and the oxalic base. The analysis of animal substances by nitric acid, reduces it to the latter base, by taking from it a great quantity of azot, the presence of which constitutes its most remark ble character.

Hal é believes that the hydro-carbonated ox d is combined with oxygen, in the stomuch and intestinal canal, whether the la ter principle be introduced with the food into the primæ viæ, or furnished by the decomposed lumours; the intestinal flinds suffer their azot to be disengaged, which is carried to the alimentary base, and replaces the carbon that had been attracted by the oxygen to form the carbonic acid. This gas, when in the lungs, and again subjected to the action of atmospheric oxygen, carries off a certain portion of its carbon; and as it disengages the azot from the venous blood, it effects a new combination of this principle with the chyle; and when propelled to the skin, the atmospheric oxygen again disengages its carbon, and comple es its azotification; perhap even the cutaneous organ answers similar purposes to the lymphatic system, as the pulmonary organ may effect to the sanguiferous system.

The asim lization of alimentary substance, therefore, takes place principally by the loss of carbon, which is replaced by azot in animal fluids These support themselves in a proper state, for, as they are continually losing the carbonic principle in the intestinal, pulmonary, and cutaneous combinations, they would be too much animalized if a newly formed chyle were not to attract the excess of azot. This theory is admitted, by its author, not to account for the formation of pho phoric calts, adeps, and abundance of other productions; but without adopting it in toro, we are induced to conclude, from the experiments and observations on which it is established, that the oxygen of the atmosp' eric ar is one of the most powerful agents employed by nature to convert the aliments on which we subject into our own preuliar substance.

Nux Moschata. Nucista. Nux myristica. Chrysobalanus Galeni. Unguentaria Assala. Nux aromatica. The nutneg.
The seed, or kennel, of the Myristica moschara of Linnæus :- foliis lanceolatis, fructu glabro. It is a spice that is well known, and has been long used both for culinary and medical purposes Distilled with water, they yield a large quantity of essential oil, resembling in flavour the spice itself; after the disullation, an insipid sebaceous matter is found swimming on the water; the decoction, inspissated, gives an extract of an unctuous, very lightly bitterish taste, and with little or no astringencv. R-ctified spirit extracts the whole virtue of nutmegs, by infusion, and elevates very little of it in distillation; hence the spirituous extract possesses the flavour of the spice in an eminent degree. Nutniegs, when heated, yield to the press a considerable quantity of limpid, yellow oil. There are three kinds of unctious substances, called oil of mace, though really expressed from the nutmeg. The best is brought from the East Indies, in stone jars; this is of a thick consistence, of the colour of mace, and has an agreeable fragrant smell; the second sort, which is paler coloured, and much inferior in quality, comes from Holland, in solid masses, generally flat, and of a square figure; the third, which is the worst of all, and usually called common oil of mace, is an artificial composition of suet, palm-oil, and the like, flavoured with a little genuine oil of nutmeg. The medicinal qualities of nutmeg are supposed to be aromatic, anodyne, stomachic and adstringent; and hence it has been much used in diarrhoas and dysenteries. To many people, the aromatic flavour of nutmeg is very agreeable: they, however, should be cautioned not to use it in large quantities, as it is apt to affect the head, and even to manifest an hypnotic power in such a degree as to prove extremely dangerous. Bontius speaks of this as a frequent occurrence in India; and Dr. Cullen relates a remarkable instance of this soporific effect of nutmeg, which fell under his own observation; and hence concludes that, in apoplectic and paralytic cases, this spice may be very improper. The officinal preparations of nutmeg are a spirit and an essential oil, and the nutmeg, in substance, roasted to render it more adstringent; both the spice itself and the essential oil enterseveral compositions, as the confectio arematica, spiritus ammoniæ aromaticus, &c.

NUX MYRISTICA. See Nux moschata. Nux persica. The walnut. Nux pistacia. See Pistachio nut. NUX PURGANS. See Ricinus major.

Nux scrapiovis. St. Ignatius's bean, NUX VOMICA. Nux metella The nux vonica, liganin colubrium, and faba sancti ignati, have been long known in the Materia Medica as narcotic passons, brought from the East Indies, while the vegetables which produced them were unknown, or at least not botanically ascertained.

By the judicious discrimination of Linnæns, the aux vomica was found to be the fruit of the tree described and figured in th Hortus M laborious, under the name of Can: ram cucurtitifera malabariansis of Prokenet: Vomica of Linnaus. Now called

Strychnos nux vonuca.

To this genus also, but upon evidence less conclusive, he likewise justly re-cered the colubrium. But the faba sancti ignatii he merely conjectured might belong to tins family, as appears by the query, An stryclini species? which subsequent discoveries have enabled us to decida in the negative; for, in the Supp. Plant, it constitutes the new genus Ignatia, which Lourero has la ely confirmed, changing the specific name amara to that of philippinica. The strychnos and ignatia are, however, nearly allied, and both rank under the order Solanacea.

Dr. Woodville has inquired thus far into the botanical origin of these productions, from finding that, by medical writers, they are generally treated of under the ame head, and in a very confused and indiscri-mitate manner. The seed of the fruit, or berry of this tree, Strychnos nux vomica, is the officinal nux vomica; it is flat, round, about an inch broad, and near a quarter of an inch thick, with a prominence in the middle on both sides, of a gray colour, covered with a kind of woolly ma ter; and internally hard and tough, like hornthe taste it is extremely bitter, but has no remarkable smell. It consists chiefly of a gummy matter, which is moderately bitter: the resinous part is very inconsiderable in quantity, but intensely bitter; hence rectified spirit has been considered its best menstruum.

Nux vomica is reckoned amongst the most powerful poisons of the narcotic kind, especially to brute animals; nor are instances wanting of its deleterious effects upon the human species. It proves fatal to dogs in a very short time, as appears by various au hornies. Hillefeld and others found that it also poisoned hares, toxes, wolves, cats, rabbits, and even some birds, as crows and ducks; and Loure ro relates, that a horse died in four hours after taking a drachm of the seed in a half-roasted

The effects of this baneful drug upon different animals, and even upon those of the same species, appear to be rather imcertain, and not always in proportion to the quantity of the poison given. With

NYM 559

some animals it produces its effects almost be administered in the character of a tonic instantaneously; with o hers, nor till after several hours, when laborious respiration, followed by torper, tremblings, coma, and convulsions, usually precede the faul spasms, or tetanus, with which this drug commonly extruguishes life.

From four cases related of its mortal effects upon human subjects, we find the symptoms corresponded nearly with those which we have here mentioned of brutes; and these, as well as the dissections of dogs killed by this poison, not shewing any injury done to the stomach or intestines, proves that the nux vomica acts immediately upon the nervous system, and destroys life by the virulence of its narcotic influence.

The quantity of the seed necessary to produce this effect upon a strong dog, as appears by experiments, need not be more than a screple; a rabbit was killed by five, and a cat by four, grains; and of the four per-ons to whom we have alluded, and who unfortunately perished by this dele crious drug, one was a garl ten years of age, to whom fifteen grains were exhibited at twice for the cure of an ague. Lors, however, tells us that he took one or two grains of it in substance, without discovering any bid effect: and that a friend of his swallowed a whole se d without injury.

In Britain, where physici as seem to observe the rule Saltem non nocere more strictly than in any other countries, the nux vom ca has been rarely, if ever, employed as a medicine. On the confinent, however, and especially in Germany, they have certainly been guided more by the axiom, " What is incapable of doing much harm, is equally unable to do much good." The truth of this remark was lately very fully exemplified by the practice of Baron Stoerck, and is farther illustrated by the mediculal character given of nux vomica, which, from the time of Gesner till that of a modern dite, has been recommended by a succession of anthors as an antidote to the plague, as a febrifuge, as a vermifuge, and as a remedy in mania, hypochondriasis, hysteria, rheumatism, gout, and canine madness. In Sweden, it has of late years been successfully used in dysentery; but Bergins, who tried its effects in this disease, says, that it suppressed the flux for twelve hours, which afterwards returned again. A woman, who took a scruple of this drug night and morning, two successive days, is said to have been serzed with convulsions and verigo, notwithstanding which the dysenteric symptons re urued, and the disorder was cured by ther medicines; but a p in in the stomach, the effect of the mix vanues, continued alterwards for a long Sime.

Bergius, therefore, thinks it should only

and a odyne, in small doses, (from five to ten grains,) and not till after proper laxatives have been employed. Loureira recommends it as a valuable internal medicine in fluor albus; for which purpose he roasts it till it becomes perfectly black and friable, which renders its medicinal use safe, without impairing its efficacy. It is said to have been used successfully in the cure of agues, and has also been reckoned a specific in pyrosis, or water brush.

NYCTALOPIA. (From we, the night, and at, an eye.) Imbecillitus oculorum of Celsus. A defect in vision, by which the patient sees little or nothing in the day, but in the evening and night sees tolerably well. The proximate cause is various:

1. From a periodical amaurosis, or gutta serena, when the blind paroxysm begins in the morning, and terminates in the evening.

2. From too great a sensibility of the retina, which cannot bear the meridian See Phobotomia.

3. From an opaque spot in the middle of the crystalline lens. When the light of the sun in the meridian contracts the pupil, there is blindness; about evening, or in more obscure places, the pupil dilates, hence the rays of light pass through the limbus of the crystalline lens.

4. From a disuse of light; thus persons who are educated in obscure prisons see nothing immediately in open meridian light; but by degrees their eyes are accustomed to distinguish objects in day-light.

5. From an immoveable mydriasis; for in this instance the pupil admits too great a quanti y of light, which the immobile pupil cannot moderate; hence the patient, in a strong light, sees little or nothing

6. From too great a contraction of the pupil. This admits a sufficiency of lucid rays in bright light, but towards night the pupil dilates more, and the patient sees

8 Nyctalopia endomica. A whole people have been nyctalops, as the Æ hiopians, Africans, Americans, and Asiatics. A great flow of tears are excreted all the day from their eyes; at night they see objects.

8. From a commotion of the eye; from which a man in the night saw all objects distinctly.

Nycrobasis. (From νυξ, the nigh βανω, to go.) W lking is the sleep. NYMPHÆ (From νυμφα, a (From vog, the night, and

(From vupoz, a waternymph; so called because it stands in the water-course.) Ale interne minores clitorichs. Colliculum Collicula. cheilides. Libia minora. Two membra. nous folds, situated within the labia majora, at the sides of the entrance of the vagina uteri.

NYMPHÆA. (From νυμφα, a waternymph; because it grows in watery places.) The name of a genus of plants in the Linnæn system. Class, Polyandria. Order, Monogynia. The water-nly.

NYMPHÆA ALBA. Leuconymphæa. Neu-

NYMPHEA ALBA. Lenconymphea, Nenuphar. Mero-lenconymphea, Write waterlily. This beautiful plant, Nymphea alba of Linneus, was formerly employed medicinally as a demolecut, and slightly anodyne remedy. It is now laid aside.

NYMPREA GLANDIFERA, Nymphea Indica, and Madraspatana. Names for the

faba Ægyptia.

NYMPHEA LUTEA. Nymphæa major hiteu of Caspar Bauhin. Y flow water-lily. Nymphæa lutea of Linaxus. This beautiful plant was employed formerly with the same intentions as the white, and, like it, is now fallen into disuse. Lindestolpe informs us, that, in some parts of Sweden, the roots, which are the strongest part, were, in times of scarcity, used as food, and did not prove unwholesome.

NYMPHEA LOTUS. The Egyptian lotus. An aquatic plant, a native of both Indies. The root is conical, firm, about the size of a middling pear, covered with a biackish bark, and set round with fibres. It has a sweetish taste, and, when boiled, or roasted, becomes as yellow within as the yolk of an egg. The plant grows in abundance on the banks of the Nile, and is there much sought after by the poor, who, in a short time, collect enough to supply their families with food for several days.

NYMPHOIDES. (From rumpair the waterlily, and adoc, likeness.) A herb resem-

bling the water-lil

NYMPHOMANIA. (From vuaqa, nympha, and uxuz, madness) Furor uterinus Called by the Arabians, Acrai. Brachuna. Arascon. Arsatum Astromania Agenus of disease in the clast Locales, and order Dysorexua, of Cullen, characterised by excessive and violent desire for cition in women. The effects, as described by Juvenal, in his sixth satire, are most humaliating to human nature. It acknowledges the same causes as satyria-is; but as females, more especially in warm

climates, have a more irritable fibre, they are apt to suffer more severely than the males.

It is a species of madness, or a high degree of hysterics. Its immediate cause is a preternatural irritability of the uterus and pudenda of women, or an unusual acrimony of the fluids in these parts. Its presence is known by the wanton behaviour of the patient; she speaks and acts with unrestrained obscenity, and, as the disorder increases, she scolds, cries, and laughs, by turns. While reason is retained, she is silent, and seems inclancholy, but her eyes discover an unusual wantonness. The symptoms are better or worse until the greatest degree of the disorder approaches, and then, by every word and action, her condition is too manifest.

NYMPHOTOMIA (From νυμφα, the nympha, an ' τεμνω, to cut.) The operation of removing the nympha when too

large.

NYSTAGMUS. (From vusua, to sleep.) A winkling of the eyes, such as happens when a person is very sleepy. Authors also define nystagmus to be an involuntary agitation of the oculary bulb. It is known by the instability or involuntary and constant motions of the globe of the eye, from one canthus to another, or in some other directions. Sometimes it is accompanied with an hippus, or an alternate and iepeated dilatation and constriction of the pupil. The species are, 1. Nystagmus, from fear. This agitation is observed under the operation for the cataract; and it is checked by persuasion, and waiting a short space of time. 2. Nystagmus, from sand, or small gravel, falling in the eye. 3. Nystagmus, from a catarrh, which is accompanied with much inflammation 4. Nystagmus, from saburra in the primæ viæ, as is observed in infants afflicted with worms, and is known by the signs of saburra. 5. Nystagmus symptomaticus, which happens in hysteric, epileptic, and sometimes in pregnancy, and is a common symptom accompanying St. Vitus's dance.

OBLIQUUS EXTERNUS ABDOMINIS. This muscle, which is so named by Morgagni, Albinus, and Winslow, is the Obliques descendens of Vesalius and Douglas, and the Obliquus major of Haller, and some others. By Dumas it is named Hiopubicosto-abdominal. It is a broad, thin muscle, fleshy posteriorly, and tendinous in its middle and lower part, and is situated immediately under the integuments, covering all the other muscles of the lower belly. It arises from the lower edges of the eight, and sometimes, though rarely, of the nine inferior ribs, not far from their cartilages, by as many distinct fleshy portions, which indigitate with corresponding parts of the serratus major anticus, and the latissimus From these several origins, the fibres of the innscle descend obliquely forwards, and soon degenerate into a broad and thin aponeurosis, which terminates in the linea alba. About an inch and a half above the pubis, the fibres of this aponeurosis separate from each other, so as to form an aperture, which extends obliquely inwards and forwards, more than an inch in length, and is wider above than below, being nearly of an oval figure. This is what is sometimes, though erroneously, called the ring of the abdominal muscles, for it belongs only to the external oblique there being no such opening either in the obliquus internus, or in the transversalis, ferior capitis, and Obliquus inferior oculi. as some writers, and particularly Douglas and Cheselden, would give us to understand. This opening, or ring, serves for the passage of the spermatic vessels in men, and of the round ligment of the uterus in women, and is of a larger size in the former than in the latter. The two tendinous portions, which, by their separation, form this aperture, are called the columns of the ring. The anterior, superior, and inner column, which is the broadest and thickest of the two, passes over the symphysis pubis, and is fixed to the opposite os pubis; so that the anterior column of the right obliquus externus intersects that of the left, and is, as it were, interwoven with it, by which means their insertion is strengthened, and their attachment made firmer. The posterior, inf rior and exterior column approaches the anterior one

low it to the os pubis of the same side. The fibres of that part of the obliquus externus, which arises from the two inferior ribs, descend almost perpendicularly, and are inserted, tendinous and fleshy, into the outer edge of the anterior half of the spine . of the ilium. From the anterior superior spinous process of that bone, the external oblique is stretched tendinous to the os pubis, forming what is called Poupart's, and sometimes Fallopius's ligament, Fallopius having first described it. Winslow, and many others name it, the inguinal ligament. But, after all, it has no claim to this name, it being nothing more than the tendon of the muscle, which is turned or folded inwards at its anterior edge. passes over the blood vessels of the lower extremity, and is thickest near the pelvis; and in women, from the greater size of the pelvis, it is longer and looser than in men. Hence we find that women are most liable to crural hernize; whereas men, from the greater size of the ring of the external oblique, are most subject to the inguinal, From this ligament, and from that part of the tendon which forms the ring, we observe a detachment of tendinous fibres, which are lost in the fascia lata, of the thigh. This may, in some measure, account for the pain which, in cases of strangulated herniz, is felt when the patient stands upright, and which is constantly relieved upon bending the thigh upwards. This muscle serves to draw down the ribs in expiration; to bend the trunk forwards when both muscles act, or to bend it obliquely to one side, and, perhaps, to turn it slightly upon its axis, when it acts singly; it also raises the pelvis obliquely when the ribs are fixed; it supports and compresses the abdominal viscera, assists in the evacuation of the urine and faces, and is likewise useful in parturition.

See Obliquus in-OBLIQUUS INFERIOR.

OBLIQUUS INFERIOR CAPITIS. This muscle, which is the obliques inferior sive major of Winslow, and the Spini axoi-do-tracheli-altoidien of Dumas, is larger than the obliquus superior capitis. It is very obliquely situated between the two first vertebræ of the neck It arises tendinous and fleshy from the middle and outer side of the spinous process of the second vertebra of the neck, and is inserted tendinous and fleshy into the lower and posterior part of the transverse process of the first vertebra. Its use is to turn the first vertebra upon the second, as upon a pivot, and to draw the face towards the shoulder.

OBLIQUUS INFERIOR OCULI. quus minor oculi of Winslow, and Maxillo scleroticien of Dumas. An oblique muscle of the eye, that draws the globe of the eye forwards, inwards, and downwards. as it descends, and is fixed behind and be. It arises by a narrow beginning from the

outer edge of the orbitar process of the superior maxillary bone, near its junction with the lachrymal bone, and running obliquely outwards, is inserted into the seleratic membrane of the eye.

OBLIQUUS INFERIOR SIVE MAJOR, See

Obliquus inferior capitis.

OBLIQUES INTERNUS. See obliquus inter-

nus obdominis.

OBLIQUUS INTERNUS ABDOMI-NIS. This muscle, which is the Obliquus ascendens of Vesalius, Douglas, and Cowper, the obliquus minor of Haller, the Obliquus internus of Winslaw, the Obliqu'es ascendens internus of Innes, and the Ilio-lumbo-costi-abdominal of Dumas, is situated immediately under the external ob-lique, and is broad and thin like that muscle, but somewhat less considerable in its extent. It arises from the spinous processes of the three inferior lumbar veriebræ, and from the posterior and middle part of the os sacrum, by a thin tendinous expansion, which is common to it and to the serratus posticus inferior, by short tendinous fibres, from the whole spine of the ilium, between its posterior tuberosity and its anterior and superior spinous process; and from two-thirds of the posterior surface of what is called Fallopius's ligament, at the middle of which we find the round ligament of the uterus in women, and the spermatic vessels in men, passing under the thin edge of this muscle; and in the latter, it likewise sends off some fibres, which descend upon the spermatic chord, as far as the tunica vaginalis of the testis, and constitute what is called the cremaster muscle, which surrounds, suspends, and compresses the testicle. From these origins, the fibres of the internal oblique run in different directions; those of the posterior portion ascend obliquely forwards, the middle ones become less and less oblique, and, at length, run in an horizontal direction, and those of the anterior portion extend obliquely downwards. The first of these are inserted, by very short tendinous fibres, into the cartilages of the fifth, fourth, and third of the false ribs; the fibres of the second, or middle porcion, form a broad tendon, which, after being inserted into the lower edge of the cartilage of the second false rib, extends towards the linea alba, and separates into two layers; the anterior layer, which is the thickest of the two, joins the tendon of the obliquus externus, and runs over the two upper thirds of the rectus muscle, to be inserted into the linea alba; the posterior layer runs under the rectus, adheres to the anterior surface of the tendon of the transversalis, and is inserted into the cartilages of the first of the false, and the last of the true ribs, and likewise into the linea alba. By this structure we may perceive that the greater part of the rectus is in-

The fibres closed, as it were, in a sheath. of the anterior portion of the internal oblique, or those which arise from the spine of the ilium and the ligamentum Fallopii, likewise form a broad tendon, which, instead of separating into two layers, like that of the other part of the muscle, runs over the lower part of the rectus, and adhering to the under surface of the tendon of the external oblique, is inserted into the fore part of the pubis. This muscle serves to assist the obliquus externus; but it seems to be more evidently calculated than that muscle is to draw the ribs downwards and backwards. It likewise serves to separate the false ribs from the true ribs. and from each other.

OBLIQUUS MAJOR ABDOMINIS. See Ob-

liquus externus abdominis.

See OBLIQUUS MAJOR CAPITIS. Obliquus inferior capitis.

OBLIQUUS MAJOR OCULI. See Obliguus

superior oculi.

OBLIQUUS MINOR ABDOMINIS. quus internus abdominis. OBLIQUUS MINOR CAPITIS. See Obliquus

superior capitis.

OBLIQUUS MINOR OCULI. See Obliquus inferior oculi. OBLIQUUS SUPERIOR CAPITIS. Ri-

olanus, who was the first that gave particular names to the oblique muscles of the head, called this muscle obliquus minor, to distinguish it from the inferior, which, on account of its being much larger, he named obliquus major. Spigelius afterwards distinguished the two, from their situation with respect to each other, into superior and inferior; and in this he is followed by Cowper and Douglas. Winslow retains both names. Dumas calls it Tra-chelo-altoido-occipital. That used by Al-binus is here adopted. This little muscle, which is nearly of the same shape as the recti capitis, is situated laterally between the occiput and the first vertebra of the neck, and is covered by the complexus and the upper part of the splenius. It arises, by a short thick tendon, from the upper and posterior part of the tranverse process of the first venebra of the neck, and, ascending obliquely inwards, and backwards, becomes broader, and is inserted, hy a broad flat tendon, and some few fleshy fibres, into the os occipitis, behind the back part of the mastaid process, under the insertion of the complexus and splenius, and a little above that of the rectus major. The use of this muscle is to draw the head backwards, and perhaps to assist in its rotatory motion.
OBLIQUUS SUPERIOR OCULI. Troch-

Obliquus major of Winslow, learis. and Optico-trochlei scleroticien of Dumas. An obtique muscle of the eye, that rolls the globe of the eye, and turns the pupil downwards and outwards. It arises like the straight muscles of the eye from the edge of the foramen opticum at the bottom of the orbit, between the rectus superior and rectus internus; from thence runs straight along the papyraceous portion of the ethmoid bone to the unper part of the orbit, where a cartilaginous trochlea is fixed to the inside of the internal angular process of the os frontis, through which its tendon passes, and runs a little downwards and outwards, enclosed in a loose membranaceous sheath, to be inserted into the sclerotic membrane.

Obliques superior sive minor. See Obliques superior capitis.

OBLIQUUS SUPERIOR SIVE TROCHLEARIS. See Obliquus superior oculi.

OBSIDIANUM. A species of glass, so called from its resemblance to a kind of stone, which one Obsidius discovered in Ethiopia, of a very black colour, though sometimes pellucid, and of a muddy water. Pliny says also, that obsidianum was a sort of colour with which vessels were glazed. Hence the name is applied, by Libavius, to glass of antimony.

OBSTETRIC. (Obstetricus; from obstetrix, a nurse) Belonging to midwifery.

OBSTIPATIO. (From obstipe, to stop up.) Costiveness. A genus of disease in the class Locales, and order Epischeses of Cullen, comprehending three species:

1. Obstipatio debilium, in weak and com-

monly despeptic persons.

2. Obstipatio rigidorum, in persons of rigid fibres, and a melancholy temperament.

3. Obstipatio obstructorum, from obstructions. See Cohea.

OBSTRUCTIA. (From obstruo, to shut up.) Medicines which close the orifices of the ducts, or vessels.

OBSTUPIFACIENTIA. (From obstupefacio,

to supefy.) Narcotics.

OUTUNDENTIA. (From obtundo, to make blunt.) Substances which sheath or blunt irritation, and are much the same as demulcents. They consist chiefly of bland, oily, or mucilaginous matters, which form a covering on inflamed and irritable surfaces, particularly those of the stomach, lungs, and anus.

OBTURATOR EXTERNUS. Extrapelvio pubi trochanterien of Dumas. This is a small flar muscle, situated obliquely at the upper and anterior part of the thigh, between the pectinalis and the fore-part of the foramen thyroideum, and covered by the adductor brevis femoris. It arises tendinous and fleshy from all the inner half of the circumference of the foramen thyroideum, and likewise from part of the obturator ligament. Its radiated fibres collect and form a strong roundish tendon, which runs outwards, and, after adhering to the capsular ligament of the joint, is inserted nto a cavity at the inner and back part of

the root of the great trochanter. The chief uses of this muscle are, to turn the thigh obliquely outwards, to assist in bending the thigh, and in drawing it inwards. It likewise prevents the capsular hgament from being pinched in the motions of the joint.

OBTURATOR INTERNUS. Marsupialis, sen obturator internus of Douglas. Marsupialis seu bursalis of Cowper, and Intra pelvio trochanterien of Dumas. A considerable muscle, a great part of which is situated within the pelvis. It arises, by very short tendinous fibres, from somewhat more than the upper half of the internal circumference of the foramen thyroideum of the os innominatum. It is composed of several distinct fasciculi, which terminate in a roundish tendon that passes out of the pelvis, through the niche that is between the spine and the tuberosity of the ischium, and, after running between the two portions of the gemini in the manner just now de-scribed, is inserted into the cavity at the root of the great trochanter, after adhering to the adjacent part of the capsular ligament of the joint. This muscle rolls the os femoris obliquely rutwards, by pulling it towards the ischiatic niche, upon the cartilaginous surface of which its tendon, which is surrounded by a membranous sheath, moves as upon a pulley.

OBTURATOR NERVE. A nerve of the thigh, that is lost upon its inner mus-

cles.

OCCIPITAL BONE. Os occipitis. Os nervosum Os basilare. memoriæ. This bone, which forms the posterior and interior part of the scull, is of an irregular figure, convex on the outside and concave internally. Its external surface, which is very irregular, serves for the attachment of several muscles. It affords several inequalities, which sometimes form two semicircular hollows, separated by a scabrous ridge. The inferior portion of the bone is stretched forwards in form of a wedge, and hence is called the cuneiform process, or basilary process. At the base of this process, situa ed obliquely on each side of the foramen magnum, are two flat, oblong protuberances, named condyles. They are covered with cartilage, and serve for the articulation of the head with the first vertebra of the neck. In the inferior portion of this bone, at the basis of the craninn, and immediately behind the cuneiform process, we observe a considerable hole, through which the medulla oblongata passes into the spine. The nervi accessorii, the vertebral arteries, and sometimes the vertebral veins likewise, pass through Man being designed for an erect posture, this foramen magnum is found nearly in the middle of the basis of the human cranium, and at a pretty equal distance from the posterior part of the occiput, and the 564

anterior part of the lower jaw; whereas in quadrupeds it is nearer the back part of the occiput. Besides this hole, there are four other smaller foramina, viz. two before, and two behind the condyles. former serve for the transmission of the ninth pair of nerves, and the two latter for the veins which pass from the external parts of the head to the lateral sinuses. On looking over the internal surface of the os occipitis, we perceive the appearance of a cross, formed by a very prominent ridge, which rises upwards from near the foramen magnum, and by two transverse sinuosities, one on each side of the ridge. cross occasions the formation of four fossæ, two above and two below the sinuosities. In the latter are placed the lobes of the cerebellum, and in the former the posterior lobes of the brain. The two sinuosities serve to receive the lateral sinuses. In the upper part of this bone is seen a continuation of the sinuosity of the longitudinal sinus; and at the basis of the cranium we observe the inner surface of the cuneiform process made concave, for the reception of the medulla oblongata. The occipital bone is thicker and stronger than any of the other bones of the head, except the petrous part of the ossa temporum; but it is of unequal thickness. At its lateral and inferior parts, where it is thinnest, it is covered by a great number of muscles. The reason for so much thickness and strength in this bone seems to be, that it covers the cerebellum, in which the least wound is of the utmost consequence; and that it is, by its situation, more liable to be fractured by falls than any other bone of the cranium. For, if we fall forwards, the hands are naturally put out to prevent the forehead's touching the ground; and if on one side, the shoulders in a great measure protect the sides of the head; but if a person fall backwards, the hind part of the head consequently strikes against the earth, and that too with considerable violence. Nature therefore has wisely constructed this bone so as to be capable of the greatest strength at its upper part, where it is the most exposed to injury. The os occipitis is joined, by means of the cuneiform process, to the sphenoid bone, with which it often ossifies, and makes but one bone in those who are advanced in life. It is connected to the parietal bones by the lamboidal suture, and to temporal bones by the additamentum of the temporal suture. The head is likewise united to the trunk by means of this bone. The two condyles of the occipital bone are received into the superior oblique processes of the atlas, or first vertebra of the neck, and it is by means of this articulation that a certain degree of motion of the head backwards and forwards is performed.

But it allows only very little motion to either side; and still less of a circular motion, which the head obtains principally by the circumvolution of the atlas on the second vertebra, as is described more particularly in the account of the vertebræ. In the fætus, the os occipitis is divided by an unossified cartilaginous substance into four parts. One of these, which is the largest, constitutes all that portion of the bone which is above the foramen magnum: two others, which are much smaller, compose the inside of the foramen magnum, and include the condyloid processes; and the fourth is the cuneiform process. This last is sometimes not completely united with the rest, so as to form one bone, before the sixth or seventh year

Occipitalis. See Occipito frontalis.

OCCIPITO FRONTALIS. Digastricus cranii. Epicranius of Albinus. Frontalis et occipitalis of Winslow and Cowper, and Occipito frontal of Dumas. A single, broad, digastric, muscle, that covers the cranium, pulls the skin of the head backwards, raises the eye-brows upwards, and, at the same time, draws up and wrinkles the skin of the forehead. It arises from the posterior part of the occiput, goes over the upper part of the os parietale and os frontis, and is lost in the eye-brows.

OCCIPUT. The hinder part of the head.

See Cuput.

Occult QUALITY. A term that has been much used by writers that had not clear ideas of what they undertook to explain; and which served therefore only for a cover to their ignorance.

OCCULT DISEASES, is likewise from the same mint as the former, occultus signifying hidden, and, therefore, nothing can be understood, when a person speaks of a hidden disease, but that it is a disease he does not understand.

Оснема. (From oxew, to carry.) A vehi-

cle, or thin fluid.

OCHETEUMA. (From oxeros, a duct.) The

OCHETUS. (From exew, to convev.) A canal or duct. The urmary, or abdominal passages.

Ocheus. (From oxew, to carry.) The bag of the scrotum.

OCHRA. (From wxgos, pale; so named because it is often of a pale colour.) 1. Ochre. Minera ferri lutea vel rubra. An argillaceous earth impregnated with iron, of a red or yellow colour. The Armenian bole, and other earths, are often adulterated with ochre.

2. The fore-part of the tibia.

Ochhus. (From axeos, pale; so called from the pale muddy colour of its flowers.) A leguminous plant, or kind of pulse. Ochrhodes. (From οχθος, importing

the tumid lips of ulcers, callous, tumid.)

An epithet for ulcers, whose lips are callous and tumid, and consequently difficult to heal.

Ocimastrum. (Dim. of ocimum, basil.)

Wild white campion, or basil.

OCIMUM. (From wwws, swift; so called from its quick growth.) Ocymum. The name of a genus of plants in the Linnæan system. Class, Didynamia. Order, Gym-1. spermia. See Basilicum.

OCIMUM BASILICUM. The systematic name of the common or citron basil. See

Basilicum.

OCIMUM CARTOPHYLLATUM. Ocimum minimum of Casper, Bauhon, and Linnæus. Small or bush basil. This plant is mildly balsamic. Infusions are drank as tea, in catarrhous and uterine disorders, and the dried leaves are made into cephalic and They are, when sternutatory powders. fresh, very juicy, of a weak aromatic and very mucilaginous taste, and of a strong and agrecable smell, improved by drying.

OCTANA. (From octo, eight.) An erratic intermitting fever, which returns every

eighth day.

OCTAVES HUMERI. The Teres Minor. OCTAVUS HUMERI PLACENTINI. The Teres

Minor. OCULARES COMMUNES. A name for the

nerves called Motores Oculorum. Ocularia. (From oculus, the eye; so called from its uses in disorders of the eye.) See Euphrasia.

OCULI ADDUCTOR. Sec Rectus internus

oculi. OCULI ATTOLLENS. See Rectus superior

Oculi Cancrorum. See Cancer.

OCULI DEPRESSOR. See Rectus inferior

OCULI ELEVATOR. See Rectus superior

OCULI LEVATOR. See Rectus superior Oculi obliquus inferior. See Obliquus

inferior oculi.

Oculi onliquus major. See Obliquus superior, oculi.

Oculi onliques minon. See Obliquus inferior oculi.

Oculus hovinus. See Proptosis. Occlus novis. See Bellis major.

Oculus nunulus. See Proptosis.

Oculus Christi, Austrian flea bane; a species of Inula.

OCULUS ELEPITANTINUS. A name given to Proptosis.

Oculus genu. The knee-pan.

OCULUS LACHRYMANS. The Epipho-

Oculus MUNDI. A species of Opal, generally of a yellowish colour. By laying in vater it becomes of an amber colour, and also transparent.

OAXISMOS. (From cost, a tooth.) A

biting sensation, pain, or itching in the

ODONTAGOGOS. (From ωs, a tooth, and αγω, to draw.) The name of an instrument to draw teeth, one of which, made of lead, Forrestus relates to have been hung up in the temple of Apollo, denoting, that such an operation ought not to be made, but when the tooth was loose enough to draw with so slight a force as could be applied with that.

ODONTAGRA. (From ofes, a tooth, and ayea, a seizure.) 1. The gout in the teeth.

2. A tooth-drawer.

ODONTALGIA. (From odes, a tooth, The tootin-ach. This and any G, pain.) well-known disease makes its attack by a most violent pain in the teeth, most frequently in the molares, more rarely in the incisorii, reaching sometimes up to the eyes, and sometimes backwards into the cavity of the car. At the same time, there is a manifest determination to the head, and a remarkable tension and inflation of the vessels takes place, not only in the parts next to that where the pain is seated, but over the whole head.

The tooth-ach is sometimes mercly a rheumatic affection, arising from cold, but more frequently from a carious tooth. It is also a symptom of pregnancy, and takes place in some nervous disorders. It may attack persons at any period of life, though it is most frequent in the young and plethoric. From the variety of causes which may produce this affection, it has been named by authors odontalgia cariosa, scorbutica, catarrhalis, arthritica, gravidarum, hysterica, stomachica, and rheumatica.

ODONTALGICA. (Medicamenta odontalgica; from of ovlanger, the tooth-ach.) Medicines which relieve the tooth-ach.

Many empirical remedies have been proposed for the cure of the tooth-ach, but have not in any degree answered the purpose. When the affection is purely rheur matic, blistering behind the ear will almost always remove it; but when it proceeds from a carious tooth, the pain is much more obstinate. In this case it has been recommended to touch the pained part with a hot iron, or with oil of vitriol, in order to destroy the aching nerve; to hold spirits in the mouth; to put a drop of oil of cloves into the hollow of the tooth, or a pill made of camphor, opium, and oleum caryophylli. Others recommend gum mastich, dissolved in oleum terebinthing, applied to the tooth upon a little cotton. The great Boerliaave is said to have applied comphor, opium, oleum caryophylli, and alkohol, upon cotton. The caustic oil which may be collected from writing paper, rolled up tight, and set fire to at the end, will sometimes destroy the exposed nervous substance of a hollow tooth. The application of radix pyrethri, by its power of stimulating the salivary glands, either in substance or in tincture, has also been attended with good effects. But one of the most useful applications of this kind, is strong nitrous acid, diluted with three or four times its weight of spirit of wine, and introduced into the hollow of the tooth, either by means of an hair pencil or a little cotton. When the constitution has had some share in the disease, the Peruvian bark has been recommended, and perhaps with much justice, on account of its tonic and antiseptic powers. When the pain is not fixed to one tooth, leeches applied to the gum are of great service. But very often all the foregoing remedies will fail, and the only infallible cure is to draw the tooth.

ODONTIASIS. (From contiae, to put forth the teeth.) Dentition, or cutting teeth.
ODONTICA. (From See, a tooth.) Reme-

dies for pains in the teeth.

ODONTIRRHEEA. (From ofes, a tooth, and gew, to flow.) Bleeding from the socket of

the jaw, after drawing the tooth.

ODONTIS. (From coss, a tooth; so called because its decoction was supposed useful in relieving the tooth-ach.) Odontitis. species of tychnis.

ODONTITIS. See Odontis.

(From also, a tooth, ODONTOGLYPHUM. and γλυφω, to scrape.) An instrument for scaling and scraping the teeth.

ODONTOID. (Odontoides; from of 85, a tooth, and sides, form, because it is shaped like a tooth.) Tooth like. A process of the second ver ebra of the neck is so called. Sec Dentatus.

ODONTOLITHOS. (From oles, a tooth, and ribos, a stone.) The tartar, or stony

crust upon the teeth.

(From odes, a tooth, ODONTOPHYIA. and  $\phi v \omega$ , to grow.) Dentition, or cutting

ODONTOTRIMMA. (From cose, a tooth, and τειδω, to wear away.) A dentifrice, or

medicine, to clean the teeth.

ODORIFEROUS GLANDS. Glandulæ odoriferæ. These glands are situated around the corona glandis of the male, and under the skin of the labia majora and nymphæ of females. They secrete a sebaceous matter, which emits a peculiar odour; hence their name.

ŒA. (Om: from ciw, to bear; so named from its muitfulness.) The service

tree.

ECONOMY, ANIMAL. (From cinos, a house, and vomos, a law.) (Economia ani-The conduct of nature in preserving animal bodies is called the animal economy.

ŒDEMA. (From obsew, to swell.) A synchym of anasarca. See Anasarca. EDEMATODES. Like to an edema.

(EDEMOSARCA. (From ownuz, a swelling, and oage, flesh.) A species of tumour mentioned by M. A. Severinus, of a middle nature, betwixt an adema, or soft tumour, and sarcoma, or hard tumour.

ENANTHE. (From ourse, wine, and ανθος, a flower; so called because its flowers smell like the vine.) 1. The botanical name of a genus of the umbelliferous plants. Class, Pentandria. Order, Digynia. 2. The pharmacopæial name of hemlock dropwort. Enanthe charophulli foliis. Enanthe crocata of Linnaus. An active poison that has too often proved fatal, by being eaten in mistake instead of water parsnep. The juice, nevertheless, cautiously exhibited, promises to be an efficacious remedy in inveterate scorbutic eruptions. The root of this plant is not unpicasant to the taste, and esteemed to be most deleterious of all the vegetables which this country produces. Mr. Howell, surgeon at Haverfordwest, relates, that "eleven French prisoners had the liberty of walking in and about the town of Pembroke. Three of them being in the fields a little before noon, dug up a large quantity of this plant, which they took to be wild celery, to eat with their bread and butter for dinner. After washing it, they all three ate, or rather tasted of the roots. As they were entering the town, without any previous notice of sickness at the stomach, or disorder in the head, one of them was seized with convulsions. The other two ran home, and sent a surgeon to him. The surgeon endeavoured first to bleed, and then to vomit him; but those endeavours were fruitless, and he died presently. Ignorant of the cause of their comrade's death, and of their own danger, they gave of these roots to the other eight prisoners, who ate of them with their dinner. A few minutes afterwards, the remaining two, who gathered the plants, were seized in the same manner as the first, of which one died; the other was bled, and a vomit, with great difficulty, forced down, on account of his jaws being, as it were, locked together. This operated, and he recovered, but was some time affected with dizzincss in his head, though not sick, or the least disor-dered in the stomach. The other eight being bled and vonited immediately were soon well. At Clonwell, in Ireland, eight boys, mistaking this plant for water-parsnep, atc plentifully of its roots. four or five hours after, the eldest boy became suddenly convulsed, and died; and before the next morning four of the other Of the boys died in a similar manner. other three, one was maniacal several hours, another lost his hair and nails, but the third escaped unhurt. Stalpaart Vary der Wicl mentions two cases of the faal effects of this root: these, however, fere

attended with great heat in the throat and stomach, sickness, vertigo, and purging; they both thed in the course of two or three hours after eating the root. Allen, in his Synopsis Medicinæ, also relates that four children suffered greatly by eating this porson. In these cases great agony was experienced before the convulsions supervened; vomitings likewise came on, which were encouraged by large draughts of oil and warm water, to which their recovery is ascribed. The late Sir William Watson, who refers to the instances here cited, also says, that a Dutchman was poisoned by the leaves of the plant boiled in pottage. It appears, from various authorities, that. most brute animals are not less affected by this poison that man; and Mr. Lightfoot informs us, that a spoonful of the juice of this plant, given to a dog, rendered him sick and stupid; but a goat was observed to eat the plant with impunity. The great virnlence of this plant has not, however, prevented it from being taken medicinally. In a letter from Dr. Poultency to Sir William Watson, we are told that a severe and inveterate cutaneous disorder was cured by the juice of the root, though not without exciting the most alarming symptoms. Taken in the dose of a spoonful, in two hours afterwards, the head was affected in a very extraordinary manner, followed with violent sickness and vomiting, cold sweats, and rigors; but this did not deter the patient from continuing the medicine, in somewhat less doses, till it effected a cure.

ENANTHE CROCATA. The systematic name of the hemlock dropwort. See Oenanthe.

ŒNANTHE CHÆROPHYLLI FOLIIS. Sec Oenanthe.

ENANTRE CICUTÆ FACIE LOUELII. The Enanthe crocata.

CENAREA. (Orepos: from araga, the cuttings of vines.) The ashes prepared of the twigs, &c. of vines.

ENELEUM: (From ones, wine, and ελαιον, oil.) A mixture of oil and wine.

Exogala. (From oree, wine, and γαλα, milk.) A sort of potion made of wine and milk. According to some, it is wine as warm as new milk.

GENOGARUM. (From onos, wine, and pagor, garum.) A mixture of wine and garum.

ENOMELI. (From ones, wine, and μελι, honey.) Mead, or wine, made of honey, or sweetened with honey.

ENORLIA. (From ones, winc.) The great jubeb-tree, the juice of whose fruit is like that of the grape.

ENOSTAGMA. (From enos, wine, and sαζω,

to distil.) Spirit of wine.

CENOTHERA. (From cayos, wine; so called because its dried roots smell like wine.) A species of lysimachia.

ENUS ANTHINOS. (From ατθο; a flower.) Flowery wine. Golen says it is Oenos anthosmias, or wine impregnated with flowers, in which sense it is an epithet for the Cyccon.

ENUS ANTHOSMIAS. (From ανθος, a flower, and οσμη, a smell.) Sweet-scented wines

ŒNUS APODÆDUS. Wine in which the dais, or tæda, are boiled.

CENUS APEZESMENUS. A wine heated to a great degree, and prescribed among other things, as garlic, salt, milk, and vinegar

ŒNUS DEUTERUS. (Δευτεgos, second.)

Wines of the second pressing.

ENUS DIACHEOMENUS. Wine diffused in larger vessels, cooled, and strained from the lees, to render it thinner and weaker; wines thus drawn off are called saccus, and saccata, from the bag through which they are strained.

ŒNUS GALACTODES. (From γαλα, milk,) Wine with milk, or wine made as warm as new milk.

Exts MALACUS. Ænus maithacus. Soft wine. Sometimes it means weak and thin, opposed to strong wine; or mild, in opposition to austere.

CENUS MELICIROOS. Wine in which is

honey.

ŒNUS GENODES. Strong wine.

ENUS STRAPHIDIOS LEUCOS. White, wine made from raisins.

ŒNUS TETHALASMENOS. Wine mixed with sea-water.

Œsορλοπυs. (From οισοφαχος, the gullet.) The muscle forming the sphincter æsophagi.

(Esornagisnus. (From οισοφαρος, the gullet.) Difficult swallowing, from spasm.

ŒSOPHAGUS. (From oue, to carry, and paya, to eat; because it carries the food into the stomach.) The membranous and muscular tube that descends in the neck, from the pharynx to the stomach. It is composed of three tonics, or membranes, viz. a common, muscular, and mucous. Its arteries are branches of the esophageal, which arises from the aorta. The veins empty themselves into the vena azygos. Its nerves are from the eighth pair and great intercostal; and it is every where under the internal or mucous membrane supplied with glands that separate the mucus of the œsophagus, in order that the masticated bole may readily pass down into the stomach.

ŒSTROMANIA. (From oisgos, the pudenda of a woman, and *mairopau*, to rage.) A furor uterinus.

ESTRUM VENEREUM. (From astrus, a gad-bee; because by its bite, or sting, it agritates cattle.) The venereal orgasm, or pleasant sensation experienced during coition.

Estre. (From ois, a sheep, and ευπος, sorde.) Oesypos. Oesypum. Oesypus. It frequently is met with in the ancient Pharmacy, for a certain oily substance, boiled out of particular parts of the fleeces of piperite. wool, as what grows on the flank, neck, and parts most used to sweat.

Offa ALBA. (From phath, a fragment, Heb.) Van Helmont thus calls the white coagulation which arises from a mixture of a rectified spirit of wine, and of urine; but the spirit of urine must be distilled from well-fermented urine; and that must be well dephlegmated, else it will not an-

OFFICINAL. (Officinalis; from officina, a shop ) Any medicine, directed by the colleges of physicians to be kept in the shops, is so termed.

Offuscatio. The same as Amaurosis. OIL. (Oleum; from olea, the olive; this name being at first confined to the oil expressed from the olive.) Oils are defined, by modern chymists, to be proper juices of a fat or unctuous nature, either solid or fluid, indissoluble in water, combustible with flame, and volatile in different degrees. They are never formed but by organic bodies; and all the substances in the mineral kingdom, which present oily characters, have originated from the action of vegetable or animal life. Oils are distinguished into fat, and essential oils; under the former head are comprehended oil of olives, almonds, rape, ben, linseed, hemp, cocoa, &c. Essential oils differ hemp, cocoa, &c. from fat oils by the following characters: their smell is strong and aromatic; their volatility is such that they rise with the heat of boiling water, and their taste is very acrid; they are likewise much more combustible than fat oils; they are obtained by pressure, distillation, &c. from strong-smelling plants, as that of peppermint, aniseed, caraway, &c. The use of fat oils in the arts, and in medicine, is very considerable; they are medicinally prescribed as relaxing, softening, and laxative remedies; they enter into many medical compounds, such as balsams, unguents, plasters, &c. and they are often used as food on account of the mucilage they contain. See Oliva. Essential oils are employed as cordial, stimulant, and antispasmodic remedies.

Oil, atherial Sec Oleam ætheriale. Oil, almond. See Amygdala. Oil of allspice. See Oleum pimente. Oil of amber. See Oleum succini.

Oil of pennyroyal. See Oleum pulegii. Oil of peppermint. See Oleum mentha

Oil, rock. See Petroleum.

Oil of spearment. See Oleum menthe viridis.

Oil, sulphurated. See Oleum sulphura-

Oil of turpentine. See Oleum teberinthe.

Ointment, See Unguentum.
OLEA. The name of a genus of plants in the Linnxan system. Class, Monandria. Order, Monogynia.

The systematic name OLEA EUROPEA. of the plant from which the olive oil is obtained. See Oliva.

OLEAMEN. (From oleum, oil.) A thin liniment composed of oils.

OLEANDER. (From olea, the olive-tree, which it resembles ) The rose bay,

OLEASTEIL (Dim. of olea, the olive-tree.) The wild olive.

OLECRANON. (From wasyn, the ulna, and apavov, the head.) The elbow, or process of the ulna, upon which a person

OLENE. (DASVN.) The cubit, or ulna. OLEOSACCHARUM. (From Oleum, oil, and saccharum, sugar.) An essential oil, ground up with sugar.

OLEUM. See Oil.

OLEUM ABIETINUM. The resinous juice which exudes spontaneously from the silver and red firs. It is supposed to be superior to that obtained by wounding the

OLEUM ETHEREUM. Æthereal oil. Oleum vini. After the distillation of sulphuric æther, carry on the distillation with a less degree of heat, until a black froth begins to rise; then immediately remove the retort from the fire, Add sufficient water to the liquor in the retort, that the oily part may float upon the surface. Szparate this, and add to it as much limewater as may be necessary to neutralize the adherent acid, and shake them together. Lastly, collect the ætherial oil which separates. This oil is used as an ingredient in the compound spirit of æther. It is a yellow colour, less volatile than æther, soluble in alkohol, and insoluble in wa-

OLEUM AMYGDALÆ. See . Imaygdala.

OLEUM ANIMALE. An empyreumatic substance, obtained by distillation from animal substances. It is sometimes exhibited as an antispasmodic and diaphoretic, in the dose of from ten to forty drops.

OLEUM ANISI. Formerly Oleum essentiule anisi, oleum e seminibus anisi. Oil of anise. The essential oil of aniseed possesses all the virtues attributed to the anisum, and is often given as a stimulant and carminative, in the dose of from five to eight drops.

mixed with an appropriate vehicle. See Anisum.

OLEUM ANTHEMIDIS. Oil of chamomile, formerly called oleum e floribus chamameli. See Chamæmelum.

OLEUM CAMPHORATUM. In retentions of urine, rheumatic pains, distentions of the abdomen from ascites; tension of the skin from abscess, this is an excellent application. See Camphora,

OLEUM CARPATHICUM. A fine essential oil, distilled from the fresh cones of the tree which affords the common turpentine.

See Terebinthina vulgaris.

OLEUM CARUL. Formerly called Oleum essentiale carui. Oleum essentiale e seminibus carui. The oil of carraways is an admirable carminative, diluted with rectified spirit into an essence, and then mixed with any proper fluid. See Carum.

OLEUM CARYOPHYLLIA ROMATICI. A stimulant and aromatic preparation of the clove. See Caryophyllum aromaticum.

OLEUM CEDRINUM, Essentia de cedro. The oil of the peel of citrons, obtained in a particular manner, without distillation, in

Italy.

OLEUM CINSAMOMI. A warm, stimulant, and delicious stomachic. Given in the dose of from one to three drops, rubbed down with some yolk of egg, in a little wine, it allays violent emotions of the stomach from morbid irritability, and is particularly serviceable in debility of the primæ viæ, after cholera morbus.

OLEUM CORNU CERVI. This is applied externally as a stimulant to paralytic affec-

tions of the limbs.

OLEUM GABIANUM. See Petroleum rubeum.

OLEUM JUNIPERI. Formerly called Oleum essentiale juniperi bacca. Oleum essentiale e baccis juniperi. Oil of juniper. Oil of juniper berries possesses stimulant, carminative, and stomachic virtues, in the dose of from two to four drops, and in a larger dose proves highly diuretic. It is often administered in the cure of dropsical complaints, when the indication is to provoke the urmary discharge.

OLEUM LAVENDULÆ. Fornerly called Oleum essentiale lavendulæ. Oleum essentiale e floribus lavendulæ. Oil of lavender. Though mostly used as a perfume, this essential oil may be exhibited internally, in the dose of from one to five drops, as a stimulant in nervous head-achs, hysteria and

debitity of the stomach.

OLEUM LAURI. Oleum laurinum. anodyne and antispasmodic application, generally rubbed on sprains and bruises unattended with inflammation.

OLEUM LIMONIS. .The easential oil of lemons possesses stimulant and s omachic powers, but is principally use! externally, mixed with ointments as a jet ime.

Linseed oil is emollient OLEUM LINI. and demulcent, in the dose of from half an ounce to an ounce. It is frequently given in the form of clyster in colics and obstipation. Cold-drawn linseed oil, with limewater and extract of lead, forms, in many instances, the best application for burns and scalds. See Linum.

OLEUM LUCII PISCIS. See Esox lu. · cius.

OLEUM MACIS. Oleum myristicæ expressum. Oil of mace. A fragrant sebaceous substance, expressed in the East Indies from the nutmeg. There are two kinds. The best is brought in stone jars, is somewhat soft, of a yellow colour, and resembles in smell the nutmeg. The other is brought from Holland, in flat square The weak smell and faint colour cake:. warrants our supposing it to be the former kind sophisticated. Their use is chiefly external, in form of plaster, unguent, or liniment.

OLEUM MALABATHII. An oil similar in flavour to that of cloves, brought from the East Indies, where it is said to be drawn from the leaves of the cinnamon

OLEUM MENTHÆ PIPERITÆ. Formerly called Oleum essentiale menthæ piperitidis, Oil of peppermint. Oil of peppermint possesses all the act ve principle of the plant. It is mostly used to make the simple water; mixed with rectified spirit it forms an essence, which is put into a variety of compounds, as sugar drops and trochisches, which are exhibited as stimulants, carminitives, and stomachies.

OLEUM MENTHÆ VIRIDIS. Formerly called Oleum essentiale menthæ sativæ. Oil of spearmint. This essential oil is mostly in use for making the simple water, but may be exhibited in the dose of from five to two drops as a carminative, stomachic, and stimulant.

Essentia neroli. The OLEUM NEROLI. essential oil of the flowers of the Seville orange tree. It is brought to us from Italy and France.

OLEUM MYRISTICE. The essential oil of nutmeg is an excellent stimulaut and aromatic, and may be exhibited in every case where such remedies are indicated, with advantage.

OLEUM MYRISTICE EXPRESSUM. This is commonly called oil of mace. See Oleum macis.

OLEUM NITRIOLI. See Sulphureous acid.

OLEUM OLIVE. See Ohva.

OLEUM OHIGANI. Formerly called Oleum essentiale origani. Oil of origanum. A very acrid and stimulating essential oil. is employed for alleviating the pain arising from caries of the teeth, and for making the simple water of marjoram.

OLEUM PALME. See Palm oil. OLEUM PETRE. See Petroleum,

OLEUM PIMENTE. Oil of allspice. stimulant and aromatic oil.

OLEUM PULEGII, Formerly called Oleum essentiale pulegii. Oil of penny-royal. stimulant and antispasmodic oil, which may be exhibited in hysterical and nervous affections.

OLEUM RICINI. See Ricinus.

OLEUM RORIS MARINI. Formerly called Olenm essentiale roris marini. Oil of rosemary. The essential oil of rosemary is an excellent stimulant, and may be given with great advantage in nervous and spasmodic affections of the stomach.

OLEUM SABINÆ. A stimulating emmenagogue: it is best administered with myrrh,

in the form of bolus.

An agreeable sti-OLEUM SASSAFRAS. mulating stomachic carminative and sudorific.

OLEUM SINAPEOS. This is an emollient oil, the acrid principle of the mustard remaining in the seed. See Sinapis.

OLEUM SUCCINI. Oleum succini rectificatum. Oil of amber is mostly used externally, as a stimulating application to paralytic limbs, or those affected with cramp and rheumatism. Hooping-cough, and other convulsive diseases, are said to be relieved also by rubbing the spine with this oil.

OLEUM SULPHURATUM. Formerly called Balsamum sulphuris simplex. Sulphurated oil. "Take of washed sulphur, four ounces; olive oil, a pint." Having heated the oil in a very large iron pot, add the sulphur gradually, and stir the mixture after each addition, until they have united. This, which was formerly called simple balsam of sulphur, is an acrid stimulating preparation, and much praised by some in the cure of coughs and other phthisical complaints.

OLEUM STRIE. A fragrant essential oil, obtained by distillation from the balm of

Gilead plant. See Moldavica.

OLEUM TEMPLINUM. Oleum templinum verum. A terebinthinate oil obtained from the fresh cones of the Pinus abies of Linnæus.

OLEUM TERRÆ. See Petroleum.

OLEUM TEREBINTHINE RECTIFICATUM. "Rectified oil of turpentine, a pint; water, four pints." Distil over the oil. Stimulant, diuretic, and sudorific virtues are attributed to this preparation, in the dose of from ten drops to twenty, which are given in rheumatic pains of the chronic kind, especially sciatica. Its chief use internally, however, is as an anthelmintic and styptic. Uterine, pulmonic, gastric, intestinal, and other hemorrhages, when passive, are more effectually relieved by its exhibition than by any other medicine. Externally it is applied, mixed with

ointments, and other applications, to bruises, sprains, rheumatic pains, indolent ulcers, burns, and scalds.

OLEUM VINI. Stimulant and anodyne in the dose of from one to four drops.

OLFACTORY NERVES. (Nervi olfactorii; from olfactus, the sense of smelling.) The first pair of nerves are so termed, because they are the organs of smelling. They arise from the corpora striata, perforate the ethmoid bone, and are distributed very numerously on the pituitary membrane of the nose.

OLIBANUM. (From lebona, Chald.) Thus. Frankincense. This drug has received different appellations, according to its different appearances; the single tears are called simply ohbanum, or thus; when two are joined together, thus masculum; and when two are very large, thus femininum; if several adhere to the bark, thus corticosum; the fine powder, which rubs off from the tears, mica thuris; and the coarser, manna thuris. The gum-resin that is so called, is the juice of the Juniperus lycia;-foliis ternis undique imbricatis ovatis obtusis. and is brought from Turky and the East Indies; but that which comes from India is less esteemed. It is said to ooze spontaneously from the bark of the tree, appearing in drops, or tears, of a pale yellowish, and sometimes of a reddish colour. Olibanum has a moderately strong and not very agreeable smell, and a bitterish, somewhat pungent taste: in chewing it sticks to the teeth, becomes white, and renders the saliva milky. Laid on a red-hot iron, it readily catches flame, and burns with a strong diffusive and not unpleasant smell. On trituration with water, the greatest part of it dissolves into a milky liquor, which, on standing, deposits a portion of resinous matter. The gummy and resinous parts are nearly in equal proportions; and though rectified spirit dissolves less of the olibanum than water, it extracts nearly all its active matter. In antient times, olibanum seems to have been in great repute in affections of the head and breast, coughs, hæmoptysis, and in various fluxes, both uterine and intestinal; it was also much employed externally. Recourse is seldom had to this medicine, which is now superseded by myrrh, and other articles of the resinous kind. It is, however, esteemed by many as an adstringent, and though not in general use, is considered as a valuable medicine in fluor albus, and debilities of the stomach and intestines: applied externally in the form of plaster, it is said to be corroborant, &c. and with this intention it forms the basis of the emplastrum thuris.

OLIGOTROPHIA. (From oxigos, small, and τεφω, to nourish.) Deficient nourishment.

OLISTHEMA. (From ολισθαινώ, to fall out.) A luxation.

OLIVA. The olive. Olea sativa. The fruit of the Olea Europea of Linnæus: folis lanceolatis integerrimis, racemis axillaribus coarctatis. The olive-tree, in all ages has been greatly celebrated, and held in peculiar estimation, as the bounteous gift of heaven; it was formerly exhibited in the religious ceremonies of the Jows, and is still considered as emblematic of peace and plenty. The varieties of this tree are numerous, distinguished not only by the form of the leaves but also by the shape, size, and colour of the fruit; as the large Spanish olive, the small oblong Provence olive, &c. &c. These, when pickled, are well known to us by the names of Spanish and French olives, which are extremely grateful to many stomachs, and said to excite appetite and promote digestion; they are prepared from the green unripe fruit, which is repeatedly steeped in water, to which some quick-lime or alkaline salt is added, in order to shorten the operation: after this they are washed and preserved in a pickle of common salt and water, to which an aromatic is sometimes added. The principal consuption, however, of this fruit is in the prepation of the common sallad oil, or oleum olivæ of the pharmacopæias, which is obtained by grinding and pressing them when thoroughly ripe: the finer and purer oil issues first by gentle pressure, and the inferior sorts on heating what is left, and pressing it more strongly. The best olive oil is of a bright pale amber colour, bland to the taste, and without any smell: it becomes rancid by age, and sooner if kept in a warm situation. With regard to its utility, oil, in some shape, forms a considerable part of our food, both animal and vegetable, and affords much nourishment. With some, however, oily substances do not unite with the contents of the stomach, and are frequently brought up by eructation; this happens more especially to those whose stomachs abound with acid.-Oil, considered as a medicine, is supposed to correct acrimony, and to lubricate and relax the fibres; and therefore has been recommended internally, to obviate the effects of various stimuli, which produce irritation, and consequent inflammation: on this ground it has been generally prescribed in coughs, catarrhal affections, and erosions. The oil of olives is successfully used in Switzerland against the tænia osculis superficialibus, and it is in very high estimation in this and other countries against nephritic pains, spasms, cholic, constipation of the bowels, &c. Externally it has been found a useful application to bites and stings of various poisonous animals, as the mad dog, several scrpents, &c. also to burns, tumours, and other affections, both by itself or mixed in liniments or poultices. Oil rubbed over the body is said to

be of great service in dropsies, particularly ascites. Olive oil enters several officinal compositions, and when united with water, by the intervention of alkali, is usually given in coughs and hoarseness.

Olive-tree. See Olida. Olives. See Oliva.

Olive, spurge See Mezereum.

OLIVANIUS. (From oliva, the olive.) Oliviformis. Resembling the olive; applied to two eminences on the lower part of the medulla oblongata, called corpora olivaria.

OLOPHLYCTIS, (From ελες, whole, and φγυκτις, a pustule.) A small hot eruption, covering the whole body; when partial, it

is called phlyctæna.

OLUSATRUM. (Id est, olus atrum, the black herb, from its black leaves) Lovage. OMAGRA. (From ωμος, the shoulder, and αγει, a seizure.) The gout in the shoulder.

OMENTITIS. (Omentitis; from omentum, the caul.) Inflammation of the omen-

tum, a species of peritonitis.

OMENTUM. (From omen, a guess; so called because the soothsayers prophesies from an inspection of this part) Epiploon. The caul. An adipose membraneous viscus of the abdomen, that is attached to the stomach, and lies on the anterior surface of the intestines. It is thin and easily torn, being formed of a duplicature of the peritoneum, with more or less of fat interposed. It is distinguished into the great omentum and the little omentum.

The omentum majus, which is also termed omentum gastrocolicum, arises from the whole of the great curvature of the stomach, and even as far as the spleen, from whence it descends loosely behind the abdominal parieties, and over the intestines to the navel, and sometimes into the pelvis. Having descended thus far, its inferior margin turns inwards and ascends again, and is fastened to the colon and the spleen, where

its vessels enter.

The omentum minus, or omentum hepaticogastricum, arises posteriorly from the trans- . verse fissure of the liver. It is composed of a duplicature of peritoneum, passes over the duodenum, and small lobe of the liver; "it also passes by the lobulus spigelii and pancreas, proceeds into the colon and small curvature of the stomach, and is implanted ligamentous into the œsophagus. It is in this omentum that Winslow discovered a natural opening, which goes by his name. If air be blown in at the foramen of Winslow, which is always found behind the lobulus spigelii, between the right side of the liver and hepatic vessels, the vena portarum and duodenum, the cavity of the omentum, and all its sacs may be distended.

The omentum is always double, and between its lamellæ closely connected by very tender cellular substance, the vessels are dristributed and the fat collected. Where the top of the right kidney, and the lobulus spigelius of the liver, with the subjacent large vessels, form an angle with the duodenum, there the external membrane of the colon, which comes from the peritoneum joining with the membrane of the duodenum, which also arises immediately from the peritoneum lying upon the kidney, enters the back into the transverse fissure of the liver, for a considerable space, is continuous with its external coat. centains the gali-bladder supports the hepatic vessels, and is very yellow and slippery. Behind this membranous production, betwixt the right lobe of the liver, hepatic vessels, vena portarum, biliary ducts, aorta, and adjacent duodenum, there is the natural opening just mentioned, by which air may be blown extensively into all the cavity of the omentum. From thence, in a course continuous with this membrane from the pylorus and the smaller curvature of the stomach, the external membrane of the liver joins in such a manner with that of the stomach, that the thin membrane of the liver is continued out of the fossa of the venal duct, across the little lobe into the stomach, stretched before the lobe and before the pancreas. This little omentum, or omentum hepotico-gustricum, when inflated, resembles a cone, and gradually becoming harder and emaciated, it changes into a true ligament, by which the esophagus is connected to the diaphragm. But the larger omentum, the omentum gastrocaslicum, is of a much greater extent. It begins at the first accession of the right gastro-epiploic artery to the stomach, being continued there from the upper plate of the transverse mesocolon; and then from the whole great curve of the stomach, as far as the spleen, and also from the right convex end of the stomach towards the spleen, until it also terminates in a ligament, that ties the upper and back part of the spleen to the stomach: this is the anterior lamina. Being continued downward, sometimes to the navel, sometimes to the pelvis, it hangs before the intestines, and behind the muscles of the abdomen, until its lower edge being reflected upon itself, ascends, leaving an intermediate vacuity between it and the anterior lamina, and is continued to a very great extent, into the internal membrane of the transverse colon, and lastly, into the sinus of the spicen, by which the large blood-vessels are received, and it ends finally on the œsophagus, under the diaphragm. Behind the stomach, and beforc the pancreas, its cavity is continuous with that of the smaller omentum. To this the omentum colicum is connected, which arises farther to the right than the first origin of the omentum gastrocolicum from the mesocolon, with the cavity of which it is continuous, but produced solely from the colon and its external membrane, which departs double from the intestine; it is prolonged, and terminates by a conical extremity, sometimes of longer, sometimes of shorter extent, above the intestinum excum. For all the blood which returns from the omentum and mesocolon, goes into the vena portarum, and by that into the liver itself. The omentum gastrocolicum is furnished with blood from each of the gastro-epiploic arteries, by many descending articulated branches, of which the most lateral are the longest, and the lowest anastomose by minute twigs with those of the colon. It also has branches from the splenic, duodenal, and adipose arteries, The omentum colicium has its arteries from the colon, as also the smaller appendices, and also from the duodenal and right epiploic. The arteries of the small omentum come from the hepatics, and from the right and left coronaries. The omentum being fat and indolent, has very small nerves. They arise from the nerves of the eighth pair, both in the greater and lesser curvatures of the stomach. The arteries of the mesentery are in general the same with those which go to the intestine, and of which the smaller branches remain in the glands and fat of the mesentery. Various small accessory arteries go to both mesocolons, from the intercostals, spermatics, lumbars, and capsular, to the transverse portion from the splenic artery, and pancreato-duodenalis, and to the left mesocolon, from the branches of the aorta going to the lumbar glands. The veins of the omentum in general accompany the arteries, and unite into simular trunks; those of the left part of the gastrocolic omentum into the splenic, and also those of the hepatigastric, which likewise sends its blood to the trunk of the vena portarum; those from the larger and right part of the gastrocolic omentum, from the omentum colicum, and from the appendices epiploides, into the mesenteric trunk. All the veins of the mesentery meet together in one wick, in the true trunk of the large vena portarum, being collected first into two large branches, of which the one, the mesenteric, receives the gastro-epiploic vein, the colica mediæ, the iliocolica, and all those of the small intestines, as far as the duodenum; the other, which going transversely, inserts itself into the former, above the origin of the duodenum, carries back the blood of the left gastric veins, and those of the rectum, except the lowermost, which belongs partly to those of the bladder and partly to the hypogastric branches of the pelvis. The vein which is called hæmorrhoidalis interna is sometimes inserted rather into the splenic than into the mesenteric vein. Has the omentum also lymphatic vessels? Certainly there are conglobate glands, both in the little omentum and in

ONO

the gastro-colicum; and ancient anatomists have observed pellucid vessels in the omentum; and a modern has described them for lacteals of the stomach.

OMENTUM COLICUM. See Omentum. OMENTUM GASTRO-COLICUM. See Omen-

OMENTUM HEPATICO-GASTRICUM. See Omentum.

OMO. Names compounded with this word belong to muscles which are attached to the scapula; from apos, the shoulder, As,

OMOCOTYLE. (From ωμως, the shoulder, and κοτυλη, a cavity.) The cavity in the extremity of the neck of the scapula, in which the head of the humerus is articulated.

OMO-HYOIDEUS. Caroco-hyoideus of Albinus and Douglas, scapulo hyodien of Dumas. A muscle situated between the os hyoides and shoulder, that pulls the os hyoides obliquely downwards. It acises broad, thin, and fleshy, from the superior costa of the scapula, near the semilunar notch, and from the ligament that runs across it; thence ascending obliquely, it becomes tendinous below the sternocleidomastoideus, and growing fleshy again, is inserted into the base of the os hyoides.

OMOPLATA. (From ωμος, the shoulder, and ωλατυς, broad.) See Seapula.

Omoplato-hvoideus. The same as Omohyoideus.

Ομοτοcos. (From ωμος, crude, and τιατω, to bring forth.) A miscarriage.

OMOTHERS. (From whos, crude, and telsa, to bruise.) Oil expressed from unripe olives.

OMPHACINUM. (From ομφακίον, the juice of unripe grapes.) Oil expressed from unripe olives.

OMPRACION. Omphacium. (From ομφακος, an unripe grape.) The juice of unripe grapes; and by some applied to that of wild apples, or crabs, commonly called Vertice.

OMPHACITIS. (From υμφακος, an unripe grape, because it resembles an unripe grape in its sour astringent state.) A small kind of gall; an excrescence from the oak.

ONPHACOMELL. (From ομφακος, an unripe grape, and μελ, honey.) A sort of oxymel made of the juice of unripe grapes and honey.

OMPHALOCARPUS. (From ομφαλος, the navel, and μαρατος, fruit; so called because its fruit resembles a navel.) Cleavers; hayriff.

OMPHALOCELE. (From ομφαλος, the navel, and καλα, a tumour.) An umbilical hernia. See Hernia.

Omerationes. (From ομφαλος, a navel; so named because the calyx is excavated in the middle like the human navel.) A plant resembling borage.

OMPHALOMANTIA. (From ομφαλος, the navel, and μαντεω, to prophesy.) The foolish vaticination of midwives, who pretend to foretel the number of the future

offspring from the number of knots in the navel.

OMPHALOS. (From ομφαλισκα, to roll up.) The navel.

OMPHALOTOMIA. (From ομφαλος, the navel, and τεμνο, to cut.) The separation of the navel-string.

ONAGRA. (From oranges, the wild ass, so called because it is said to tame wild beasts.) Also a name for the rheumatism in the ellow.

ONEIRODYNIA. (From overgov, a dream, and odown, anxiety.) Disturbed imagination during sleep. A genus of disease in the class Neuroses, and order Vesaniæ of Cullen, containing two species,

1. Oneirodynia activa, walking in the sleep.

2. Oneirodynia gravans, the incubus, or

night-mare. See Night-mare.
ONEIROGMOS. (From overgog to, to dream.)

Venereal dreams.
ONEHROGONOS. (From oragos, a dream, and you, the seed.) So the Greeks call an occasional emission of the semen in sleep,

when it only happens rarely.

Onion. See Cepa.

Onion, sea. See Scilla.

Onis. (From over, an ass.) the dung of an ass. It was in repute with Hippocrates.

Oniscus- (From over, an ass; so called because like the ass it requires much beating before it is useful.) The stock-fish. Also the slow-worm.

ONISCUS ASELLUS. The systematic name of the woodlouse. See Millepedes.

ONITIS. (From 6065, an ass, because asses covet it.) The origanum plant.

Onorrents. (From ever, an ass, and βενχω, to bray; so called, according to Blanchard, because the smell or taste makes asses bray.) Holy hay: saintfoin; cockshead vetch.

ONONIS. (From cros, an ass, because it interrupts asses when at plough.) 1. The name of a genus of plants in the Linnaen system. Class, Diadelphia. Order, Decandrio. 2. The pharmacopoial name of the Resta. bovis. Arresta bovis. Remora aratri. Rest harrow. The roots of this plant, Ononis spinosa, vel arvensis of Linnaeus, have faint unpleasant snell, and a sweetish, bitterish, somewhat nauseous taste. Their active matter is confined to the cortical part, which has been sometimes given in powder, or other forms, as an aperient and diuretic.

Ononis arvensis. The systematic name of the rest harrow. See Ononis.

Ononis srinosa. The systematic name of the rest harrow. See Ononis.

Onopordium acanthium. (Oyomogdor; from ores, an ass, and negdo, to break wind; so named from its being much coveted by asses, and from the noise it makes upon pressure.) The systematic name of the cotton-thistle. See Carduus tormentosus.

ONOSMA ECHIOIDES. The systematic name of the plant whose root is called anchusa lutea in some pharmacopæias. It is supposed to possess menagogue virtues.

ONYCHIA. (From ovue, the nail.) A whitlow at the side of the finger nail.

ONYX. Ovig. Unguis. An abscess, or collection of pus between the lamella of the cornea; so called from its resemblance to the stone called onyx. The diagnostic signs are, a white spot or speck, prominent, soft, and fluctuating. The species are:

1. Abscessus superficialis, arising from inflammation, not dangerous, for it vanishes when the inflammation is resolved by

the use of astringent collyria.

2. Abscessus profundus, or a deep abscess, which is deeper seated between the lamellæ of the cornea, sometimes breaking internally, and forming an hypopium: when it opens externally it leaves a fistula upon the cornea; whenever the pus is exsecuted, there remains a leucoma.

ODEIDES. (From wor, an egg, and woo, a likeness.) An epithet for the aqueous

humour of the eye.

Ophioglossum, and ειδος, a likeness.) A fungus resembling the adder's tongue.

OPINOGLOSSUM. (From οφε, a serpent, and γλωσσα, a tongue; so called from the resemblance of its fruit.) Adders tongue.

Ophioriniza mungos. The systematic

name of the plant whose root is called radix serpentum in the pharmacopæias. See

Mungos radix.

Ophioscoronon. (From opic, a serpent, and oxogoton, garlic, so named because it is spotted like a serpent.) Broad-leaved garlic.

Ophiostaphylum. (From οφις, a serpent, and σαφυλή, a berry, so called because serpents feed upon its berries.) White briony.

See Bryonia.

Ophication serpentinum. The systematic name of the tree whose wood is termed lignum serpentinum. See Serpentinum ignum.

OPHRYS. (Ocque. The lowest part of the forehead, where the eye-brows grow. Also an herb so called because its juice was used to make the hair of the eye-brows black.

OPHTHALMIA. (From οφθαλμος, the Ophthalmitis. An inflammation of the membranes of the eye, or of the whole The symptoms which bulb of the eye. characterize this disease are a preternatural redness of the tunica conjunctiva, owing to a turgescence of its blood-vessel; pain and heat over the whole surface of the eye, often attended with a sensation of some extraneous body between the eye and eyelid and a plentiful effusion of tears. All these symptoms are commonly increased by motion of the eye, or its coverings, and likewise by exposure to light. We judge

of the depth of the inflammation by that degree of pain produced by light thrown upon the eye. When the pain produced by light is considerable, we have much reason to imagine that the parts at the bottom of the eye, and especially the retina, are chiefly affected, and, vice versa, when the pain is not much increased by this exposure, we conclude with great probability that the inflamation is confined perhaps entirely to the external covering of the eye. In superficial affections of this kind too the symptoms are in general local; but, whenever the inflammation is deep seated, it is attended with severe shooting pains through the head, and fever to a greater or less degree commonly takes place. During the whole course of the disease there is for the most part a very plentiful flow of tears, which frequently become so hot and acrid as to excoriate the neighbouring parts, but it often happens after the disease has been of some duration, that together with the tears a considerable quantity of a yellow purulent-like matter is discharged, and when the inflammation has either spread to the eyelids, or has been seated there from the beginning, as soon as the tarsi becomes affected a discharge takes place of a viscid glutinous kind of matter, which greatly adds to the patient's distress, as it tends to increase the inflammation by cementing the eye-lids so firmly together as to render it extremely difficult to separate

Ophthalmia is divided into external, when the inflammation is superficial, and internal, when the inflammation is deep seated, and the globe of the eye is much affected.

In severe ophthalmia two distinct stages are commonly observable; the first is attended with a great deal of heat and pain in the eye, and considerable febrile disorder; the second is comparatively a chronic affection without pain and fever. The eye is merely weakened, moister than in the healthy state, and more or less red.

Ophthalmia may be induced by a variety of exciting causes as operate in producing inflammation in other situations. A severe cold in which the eyes are affected at the same time with the pituitary cavities, fauces, and trachea; change of weather; sudden transition from heat to cold; the prevalence of cold winds, residence in damp or sandy countries, in the hot season; exposure of the eyes to the vivid rays of the sun; are causes usually enumerated, and considering which, it does not seem extraordinary that ophthalmia should often make its appearance as an epidemic, and afflict persons of every age and sex. Besides these exciting causes, writers also generally mention the suppression of some habitual discharge, as of the menses, bleedings from the nose, from hæmorrhoids, &c. Besides which, inflammation of the eyes may be

occasioned by the venereal and scrophulous virus.

OPHTHALMIC GANGLION. Ganglion ophthalmicum. Lenticular ganglion. This ganglion is formed in the orbit, by the union of a branch of the third or fourth pair with the first branch of the fifth pair of nerves.

OPHTHALMIC NERVE. Nervus opthalmicus. Orbital nerve. The first branch of the ganglion or expansion of the fifth pair of nerves. It is from this nerve that a branch is given off, to form, with a branch of the sixth, the great intercostal nerve.

OPTHALMICI EXTERNI. See Metores oculorum.

OPHTHALMODYNIA. (From oφθαος, an eye, and oθουπ, pain.) A vehement pain in the eye, without, or with very little redness. The sensation of pain is various, as itching, burning, or as if gravel were between the globe of the eye and ids. The species are:

1. Ophthalmodinia rheumatica, which is a pain in the muscular expansions of the globe of the eye, without redness in the albuginea. The rheumatic inflammation is serous, and rarely produces redness.

2. Ophthalmodynia periodica, is a periodical pain in the eye, without redness.

3. Ophthalmodnyia spasmodica, is a pressing pain in the bulb of the eye, arising from spasmodic contractions of the muscles of the eye, in nervous, hysteric, and hypochondriac persons. It is observed to terminate by a flow of tears.

4. Ophthalmodynia from an internal inflammation of the eye. In this disorder, there is a pain and sensation as if the globe was

pressed out of the orbit.

5. Ophthalmodynia hydropthalmica. After a great pain in the inferior part of the os frontis, the sight is obscured, the pupil is dilated, and the bulb of the eye appears larger, pressing on the lid. This species is likewise perceived from an incipient hydropthalmia of the vitrcous humour.

 Ophthalmodynia arenosa, is an itching and sensation of pain in the eye, as if sand or gravel were lodged between the globe

and lid.

7. Ophthalmodynia symptomatica, which is a symptom of some other eye-disease, and is to be cured by removing the exciting cause.

8. Ophthalmodynia cancrosa, which arises from cancerous acrimony deposited in the

eye, and is rarely curable.

Ophthalmoronia. (From οφθαλμος, the eye, and ποιω, to labour.) An intense pain in the eye, whence the light is intolerable.

OPHTHALMOPYOSIS. (From οφθαλμος, an eye, and πλοτις, a fall.) A falling down of the globe of the eye on the cheek, canthus, or upwards, the globe itself being

scarce altered in magnitude. The cause is a relaxation of the muscles, and ligamentous expansions of the globe of the eye. The species are:

1. Ophthalmoptosis violenta, which is generated by a violent contusion or strong stroke, as happens sometimes in boxing. The eye falls out of the socket on the clieck or canthus of the eye, and from the elongation and extension of the optic nerve occasions immediate blindness.

2. Ophthalmoptosis, from a tumour within the orbit. An exostosis, tophs, abscess, encysted tumours, as, atheroma, lygroma, or schirrhus, forming within the orbit, induration of the orbital atleps, may throw the bulb of the eye out of the socket upwards, downwards, or towards either canthus.

 Ophthalmoptosis paralytica, or the paralytic ophthalmoptosis, which arises from a paralysis or palsy of the recti muscles, from hence a stronger power in the oblique

muscles of the bulb.

4. Ophthalmoptosis staphylomatica, when the staphyloma depresses the inferior eye-

hid and extends on the cheek.

OPIATE. (Medicamentum opiatum; from the effects being like that of opium.) A medicinc that procures sleep, &c. See Anodynes.

Orion. (Oriov.) Opium.

Orismus. (From 6710), opium.) An opiate confection.

OPISTHEMAR. (From structure, backwards and  $\theta w \alpha g$ , the palm.) The back part of the palm.

OPISTHOGRANIUM. (From controls, back. ward, and season, the head.) The occiput, or hinder part of the head.

OPISTHOCKPHOSIS. (From οπισθεν, backward, and κυφωσις, a gibbosity.) A curved

spine

OPISTHOTONOS. (From οπισθεν, backwards, and τείνου, to draw.) A fixed spasm of several muscles, so as to keep the body in a fixed position, and bent backwards. Cullen considers it as a variety of tetantus. See Tetanus.

OPIUM. (Probably from \$\pi\pi\sigma\

The species of poppy is the papaver somniferum, of Linnaus:—calycibus capsulisque glabris foliis amplexicaulibus incisis. It is brought from Turkey, Egypt, the East Indies, and other parts of Asia, where poppies are cultivated for this use in fields, as corn among us. The manner in which it is collected has been described long ago by . OPIUM.

Kæmpfer and others; but the most cir- spissated by a gentle heat; this was for-cumstantial detail of the culture of the merly called meconium, in distinction from poppy, and the method of procuring the opium, is that given by Mr. Kerr, as practised in the province of Bahar; he says, "The field being well prepared by the plough and harrow, and reduced to an exact level superficies, it is then divided into quadrangular areas of seven feet long, and five feet in breadth, leaving two feet of interval, which is raised five or six inches, and excavated into an aqueduct for conveying water to every area, for which purpose they have a well in every cultivated field. The seeds are sown in October or November. The plants are allowed to grow six or eight inches distant from each other, and are plentifully supplied with water; when the young plants are six or eight inches high, they are watered more sparingly. But the cultivator spreads all over the areas a nutrient compost of ashes, human excrements, cowdung, and a large portion of nitrous earth, scraped from the highways and old mud walls. When the plants are nigh-flowering, they are watered profusely, to increase the juice.

When the capsules are half grown, no more water is given, and they begin to col-

lect the opium.

At sunset they make two longitudinal double incisions upon each half ripe capsule, passing from below upwards, and taking care not to penetrate the internal cavity of the capsule. The incisions are repeated every evening until each capsule has received six or eight wounds; then are they allowed to ripen their seeds. The ripe capsules afford little or no juice. If the wound was made in the heat of the day, a cicatrix would be too soon formed. The night dews, by their moisture, favour

the exstillation of the juice. Early in the morning; old women, boys, and girls, collect the juice by scraping it off the wounds with a small iron scoop, and deposit the whole in an earthen pot, where it is worked by the hand in the open sunshine, until it becomes of a considerable spissitude. It is then formed into cakes of a globular shape, and about four pounds in weight, and laid into little earthen basins to be further exsiccated. These cakes are covered over with the poppy or tobacco leaves, and dried until they are fit for sale. Opium is frequently adulterated with cow-dung, the extract of the poppy plant procured by boiling and various other substances which they keep in secresy."

This process, however, is now but rarely practised, the consumption of this drug being too great to be supplied by that me-

thod of collection.

The best sort of the officinal opium is the expressed juice of the heads, or of the heads and the upper part of the stalks inthe true opium, or juice which issues spon-

taneously.

The inferior sorts (for there are considerable differences in the quality of this drug,) are said to be prepared by boiling the plant in water and evaporating the strained decoction; but as no kind of our opium will totally dissolve in water, the juice is most probably extracted by expression. Newman was informed by some Turks at Genoa and Leghorn, that in some places the heads, stalks, and leaves are committed to the press together, and that this juice inspissated affords a very good opium.

On this head Dr. Lewis remarks, that the point has not yet been fully determined. It is commonly supposed, that whatever preparations the Turks may make from the poppy for their own use, the opium brought to us is really the milky juice collected from incisions made in the heads, as described by Kæmpfer. It is certain that an extract made by boiling the heads, or the heads and stalks in water, is much weaker than opium; but it appears also, that the pure milky tears are considerably stronger.

The principles separable from opium are, a resin, gum, a minute proportion of saline matter, water and earth, which are intimately combined together, insomuch that all the three dissolve almost equally in water and in spirit. It is probably to the saline principle Nicholson observes in this and other vegetables that the intimacy of

union is in great measure to be ascribed.

Four ounces of opium, treated with alkohol, yielded three ounces and four scru-ples of resinous extract; five drachms and a scruple of insoluble impurities remaining. On taking four ounces more, and applying water at first, Newman obtained ounces five drachms and one scruple of gummy extract; the insoluble part amounting here to seven drachms and a scruple. In distillation, alkohol brought over little or nothing; but the distilled water was considerably impregnated with the peculiar ill smell of opium.

From this analysis may be estimated the effects of different solvents upon it. Alcohol and proof spirit dissolving its resin, afford tinctures possessing all its virtues. Water dissolves its gummy part, which is much less active, but a part of the resin is at the same time taken up by the medium of the gum. Wines also afford solutions possessing the virtues of opium. negar dissolves its active matter, greatly impairs its powers.

The use of this celebrated medicine, though not unknown to Hippocrates, car. be clearly traced to Diagoras, who was nearly his cotemporary, and its importance has ever since been gradually advanced by

OPIUM. 5.77

succeeding physicians of different nations. Its extensive practical utility, however, has not been long well understood; and in this country perhaps may be dated from the time of Sydenham. Opinm is the chief narcotic now employed; it acts directly upon the nervous power, diminishing the sensibility, irritability, and mobibility of the system; and, according to Cullen, in a certain manner suspending the motion of the nervous fluid to and from the brain, and thereby inducing sleep, one of its principal effects. From this sedative power of opinin, by which it allays pain, inordinate action, and restlessness, it naturally follows that it may be employed with advantage in a great varie-Indeed, there is scarcely ty of diseases. any disorder, in which, under some circumstances, its use is not found proper; and though in many cases it fails of producing sleep, yet, if taken in a full dose, it occasions a pleasant tranquillity of mind, and a drowsiness, which approaches to sleep, and which always refreshes the patient. Besides the sedative power of opium, it is known to act more or less as a stimulant, when given in a larger dose, exciting the motion of the blood. By a certain conjoined effort of this sedative and stimulint effect, opium has been thought to produce intoxication, a quality for which it is much used in eastern countries.

The principal indications which opium is capable of fulfilling are, supporting the actions of the system, allaying pain and irritation, relieving spasmodic ac ion, inducing sleep, and checking morbidly increased secretions. It is differently administered, as it is designed to fulfil one or

other of these indications.

Where opium is given as a stimulus, it ought to be administered in small doses frequently repeated, and slowly increased, as by this mode the excitement it produces is best kept up. But when the design is to mitigate pain or irritation, or the symptoms arising from these, it ought to be given in a full dose, and at distant intervals, by which the state of diminished power and sensibility is most completely induced.

One other general rule, with respect to the administration of opium, is, that it ought not to be given in any pure inflammatory affection, at least until evacuations have been used, or unless means are employed to determine it to the surface, and

produce a diaphoresis.

In continued fevers, not of the pure inflammatory kind, opium is administered sometimes as a general stimulus, and at other times to allay irritation. The great practical rule in such cases is, that it ought to be given in such quantities only, that the pulse becomes slower and fuller from its operation. Its exhibition is improper, where local inflammation, especially of the brain, or of its membranes, exists.

La micrimition fever, the exhibition of an opiate renders the paroxysms milder, and facilitates the cure. Dr. Cullen reconmends the mion of opium with bark, which enables the stomach to bear the latter in larger doses, and adds considerably to its efficacy.

In the greater number of the profluvia catarrh cholera, opium is employed to lessen the discharge, and is frequently the principal remedy in effecting the cure. In passive, hæmorrhagy, it proves useful by its stimulant power. In retrocedent gout it is used as a powerful stimulant.

In convulsive and spasmodic diseases it is advantageously administered, with the view of relieving symptoms, or even of effecting a permanent cure, and in several of them it requires to be given to a very great

extent.

In lues venerea it promotes the action of mercury, and relieves the irritation arising either from that remedy, or from the disease.

In the year 1779, opium was introduced into practice as a specific against the lues venerea. It was employed in several of the military hospitals, where it acquired the reputation of a most efficacious remedy; and Dr. Michaelis, physician of the Hessian forces, published an account of a great number of successful experiments made with it, in the first volume of the Medical Communications in the year 1784. Opium was afterwards given as an antivenereal remedy in some foreign hospitals. Many trials were also made of its virtues in several of the London hospitals, and in the Royal Infirmary at Edinburgh. Very favourable reports of its efficacy in removing venereal complaints were published by different practitioners; but, at the same time, so many deductions were to be made, and so many exceptions are to be admitted, that it required little sagacity to discover, that most of the advocates for this medicine reposed by a slender and fluctuating confidence in its antivenereal powers. Mr. Pearson made several experiments on the virtues of opium in lues venerea, at the Lock Hospital, in the years 1784 and 1785; and published a narrative of its effects, in the second vo-lume of the Medical Communications. "The result of my experiments," says he, " was very unfavourable to the credit of this new remedy; and I believe that no surgeon in this country relies on opium as a specific against the venereal virus. I have been long accustomed to administer opium with great freedom during the venereal course; and the experience of nearly twenty years has taught me, that, when it is combined with mercury, the proner efficacy of the latter is not in any measure increased; that it would not be safe to rely

OPIUM.

upon a smaller quantity of the mineral its most valuable properties would be able specific, nor to contract the mercurial course within a shorter limit than where no opium has been employed. This representation will not, I presume, admit of controversy; yet we frequently hear people expressing themselves upon this head, as if opium manifested some peculiar qualities in venereal complaints, of a distinct nature from its well known narcotic properties, and thus afforded an important aid to mercury in the removal of lues venerea." Perhaps it may not be unuseful to disentangle this subject from the perplexity in which such indefinite language necessarily involves it. Opiam, when given in conjunction with mercury, by diminishing the sensibility of the stomach and bowels, prevents many of those inconveniences which this mineral is apt to excite in the primæ viæ; and thus its admission into the general system is facilitated. Mercury will likewise often produce a morbid irritability, accompanied with restlessness and insomnolescence, and it sometimes renders venereal sores painful, and disposed to spread. These accidental evils, not necessarily connected with the venereal disease, may be commonly alleviated, and often entirely removed, by a judicious administration of opium; and the patient will consequently be enabled to persist in using the mineral specific. It however, must be perfectly obvious, that opium, in conferring this sort of relief, communicates no additional virtues to mercury, and that, in reality, it assists the constitution of the patient, not the operation of the medicine with which it is combined. The salutary effects of mercury, as an antidote, may be diminished or lost by the supervention of vomiting, dysentery, &c. Opium will often correct these morbid appearances, and so will spices, wine, an appropriate diet, &c. yet it would be a strange use of words to urge, wherever these articles of food were beneficial to a venereal patient, that they concurred in augmenting the medicinal virtues of mcrcury. It may be supposed that the majority of medical men would understand, by the terms " to assist a medicine in curing a contagious disease," that the drug conjoined with the specific actually increased its medicinal efficacy; whereas, in the instances before us, it is the human body only, which has been aided to resist the operation of certain noxious powers, which would render a preference in the antidote prejudicial or impossible. The soothing qualities of this admirable medicine can scarcely be estimated too highly. Yet we must beware of ascribing effects to them which have no existence; since a confidence in the antivenereal virtue of opium would be a source of greater mischief, than

to compensate.

Opium is employed with laxatives in colic, and often prevents ileus and inflammation, by relieving the spasm.

It is often given to promote healthy suppuration, and is a principal remedy in arresting the progress of gangrene.

The sudorific property of opium is justly considered of considerable power, more especially in combination with ipecacuan or antimony. The combined powder of ipecacuan, consisting of one part of ipecacuan, one part of opium, and eight of sulphat of potash, is a very powerful sudorific, given in a dose from 15 to 25 grains. The combination of opium with antimony is generally made by adding 30 to 40 drops of antimonial wine to 25 or 30 drops of tincture of opium, and forming them into a dranght.

Opium, taken into the stomach in immoderate doses, proves a narcotic poison, psoducing vertigo, tremors, convulsions, delirium, stupor, stertor, and, finally, fatal

apoplexy.

Where opium has been taken so as to produce these dangerous consequences, the contents of the stomach are first to be evacuated by a powerful emetic, as a solulution of the sulphat of zinc. draughts of vinegar, or any of the native vegetable acids, are then to be swal-lowed. Moderate doses of brandy, or a strong infusion of coffee, have also been found useful.

Respecting the external application of opium, authors seem not sufficiently agreed. Some allege, that when applied to the skin it allays pain and spasm, procures sleep, and produces all the salutary or dangerous effects which result from its internal use; while others say, that thus apphed it has little or no effect whatever. It has also been asserted, that when mixed with caustic it diminishes the pain which would otherwise ensue; and if this be true, it is probably by decreasing the sensibility of the part. Injected by the rectuin, it has all the effect of opium taken into the stomach; but to answer this purpose, double the quantity is to be employed. Applied to the naked nerves of animals, it produces immediate torpor and loss of power in all the muscles with which the nerves communicate.

The requisite dose of opium varies in different persons, and in different states of the same person. A quarter of a grain will in one adult produce effects which ten times the quantity will not do in another; and a dose that might prove fatal in cholera or colic, would not be perceptible in many cases of tetanus, or mania. The lowest fatal dose, to those unaccustomed to take it, seems to be about four grains; but a dangerous dose is so apt to produce

vomiting, that it has seldom time to occasion death. When given in too small a dose, it often produces disturbed sleep, and other disagreeable consequences; and in some cases it seems impossible to be made to agree in any dosc or form. Often, on the other hand, from a small dosc, sound sleep and alleviation of pain will be produced; while a larger one occasions vertigo and delirium. Some prefer the reperition of small doses; others the giving a full dose at once: its operation is supposed to last about eight hours; this however must depend upon circumstances. The usual dose is one grain. The officinal preparations of this drug are numerous. The following are among the principal: Opium purificatum, pilula ex opro, pulvis opiatus, tinetura opii, tinetura opii camphorata, and confectio opii: it is also an ingredient in the pulvis ipecacuanha compositus, electuarium japonicum, pulvis e cretacompositus, &c.

OPOBALSAMUM. (From orros. juice, and Panoapor, balsant.) See Bulsamum Gilea-

OPOCALPASON. (From ores, juice, and κιλπασοςα, a tree of that name.) Opicurpison. The juice of a tree called Calpast. It resembles myrrh, but is poisonous.

OPUDEOCELE. A ruptue through the foramen ischii, or into the labia pudendi. OPODELDOC. A term of no meaning,

frequently mentioned by Paracelsus. Formerly it signified a plaster for all external injuries, but now is confined to a campho-

rated soap liniment.

OPOPANAX. (From oros, juice, and Tavas, the panacea.) The plant from whence the gum is produced is known by the names of opoponacum, panax heracleum, panax costinum, panax pastinacea, kyna, Hercules all heal, and opoponaxwort. Pastinaca opopanax of Linnaus; foliis pinnatis, foliolis basi antica excisis. Opopanax is the gumni-resinous juice obtained by means of incisions made at the bottom of the stalk of the plant, from which it gradually exudes, and by undergoing spontancous concretion, assumes the appearance under which we have it imported from Turkey, and the East Indies, viz. sometimes in little drops or tears, more commonly in irregular lumps, of a reddish yellow colour on the outside, with specks of white; internally of a paler colour, and frequently variegated with large white pieces. Opoponax has a strong disagreeable smell, and a bitter, acrid, somewhat nauscous tastc. only employed in the present practice as an antispasmodic, in combination with other medicines, although it was formerly in high estimation as an attenuant, deobstruent, and aperient. Its antispasmodic virtues arc less powerful than galbanum,

and more so than ammoniacum. It has no place in the Edinburgh Pharmacopæia, but is directed by the London College in the pilula galbani composita.

OPOPIA (From orrowal, to see.) The

bones of the eyes.

OPORICE. (From oroga, autumnal fruits.) A conserve made of ripe fruits.

OPPHATIO. (From oppile, to shut up.) Oppulation is a close kind of obstruction; for, according to Rhodius, it signifies, not only to shut out, but also to fill.

OPPILATIVA. (From oppilo, to shut up.) Medicines or substances which shut ap the

Sec Flexor ossis OPPONENS POLLICIS.

metacarpi pollicis.

OPPRESSIO. The catalepsy, or any pressure upon the brain.

Opsigonos. (From it, late, and pivoual, to be born.) A dens sapientiæ, or late cut tooth.

OPTIC NERVES. (Nervi optici, from official, to sec: because they are the organs of sight.) The second pair of nerves of the brain, they arise from the thalami, nervorum opticorum, perforate the bulb of the eye, and in it form the retina.

OPUNTIA. (.16 opunte, from the city Opus, near which it flourished.) prickly leaves of this plant, Cacius opuntia of Linnzus, abound with a mucillagmous matter, which is esteemed in its native countries an emollient, in the form of poultice.

Orache, stinking. See Atriplex fatida.

Orange. See Aurantium.

Orange, Seville. See Aurantium.
Orange, shaddock. See Shaddock.
ORBICULARE OS. (Orbicularis,

shaped like a ring, from orbiculus, a little ring.) Os pisiforme. A name of a bone of the carpus. Also a very small round bone, not larger han a pin-head, that belongs to the internal ear.

ORBICULARIS ORIS. (Musculus orbicularis oris, from orbiculus, a little ring; so called from its shape.) Sphincter laborium of Douglass, semi orbicularis of Winslow, constrictor oris of Cowper, and labial of Dumas. A muscle of the mouth, formed in a great measure by those of the lips; the fibres of the superior descending, those of the inferior ascending, and decussating each other about the corner of the mouth; they run along the lip to join those of the opposite side, so that the fleshy fibres appear to surround the mouth like a sphincter. Its use is to shut the mouth, by contracting and drawing both lips together, and to counteract all the muscles that assist in forming it.

ORBICULARIS PALPEBRARUM. Or. bicularis, scil. musculus. Orbicularis palpebrarum ciliaris of authors, and maxillo palpebral of Dumas. A muscle common to both the cyclids. It arises by a number

of fleshy fibres from the outer edge of the orbitar process of the superior maxillary bone, and from a tendon near the inner angle of the eye; these fibres run a little downward, and outwards, over the upper part of the cheek, below the orbit, covering the under eyelid, and surround the external angle, being closely connected only to the skin and fat; they then run over the superciliary ridge of the os frontis, towards the inner canthus, where they mix with the fibre of the os oecipito-frontalis and corrugator supercilii: then eovering the upper eyelid, they descend to the inner angle, opposite to their inferior origin, and firmly adhere to the internal angular process of the os frontis, and to the short round tendon which serves to fix the palpebræ and muscular fibres arising It is inserted into the nasal process of the superior maxillary bone by a short round tendon, covering the anterior and upper part of the lachrymal sac, which tendon can be easily felt at the inner canthus of the eye. The use of this muscle is to shut the eye, by drawing both lids together, the fibres contracting from the outer angle towards the inner, press the eyeball, squeeze the lachrymal gland, and convey the tears towards the puncta lachrymalia.

ORBICULARIS PALPERRARUM CILIARIS. See

Orbicularis palpebrarum.

ORBITS. Orbita. The two cavities under the forehead, in which the eyes are situated, are so termed. The angles of the orbits are called canthi. Each orbit is composed of seven bones, viz. the frontal, maxillary, jugal, lachrymal, ethmoid, palatine, and sphanoid The use of this bony socket is to maintain and defend the organ of sight, and its adjacent parts.

ORCHEA. (From ogxis, a testicle.) Ga-

len says it is the scrotum.

ORCHIS. (From opeyopau, to desire.)

1. A testicle.

2. The name of a genus of plants in the Linnæan system. Class, Gyuandria. Order, Diandria.

ORCHIS BIFOLIA. The systematic name of the butterfly orchis. See Satyrion.

ORCHIS MASCULA The systematic name

of the male orchis. See Satyrion.
Onemis Monio. The systematic name of the orchis from whose root the salep is made. See Salep,

ORCHITIS. (From ogxis, a testicle.)

See Hernia humoralis.

Orchos. (From ogxos, a plantation or orchard; so called from the regularity with which the hairs are inserted.) extremities of the eye-lids, where the eyelashes grow.

ORCHOTOMY. (From ogxis, a testicle, and reuvo, to cut.) Castration. The operation of extracting a testicle.

(From opos, a mountain, OREOSELINUM. and σελινον, parsley, so named because it grows wild upon mountains.) Black mountain parsley. The root and seed of this plant, Athaminta oreoselinum of Linnæus, foliolis divaricatis, as well as the whole herb, were formerly used medicinally. Though formerly in so high estimation as to obtain the epithet of polychesta, this plant is seldom used in the practice of the present day. An extract and tincture prepared from the root were said to be attenuant aperient, deobstruent, and lithoutriptic. The oil obtained by distillation from the seed was esteemed to allay the toothach; and the whole was recommended as an antiscorbutic and corrobo-

ORESTION. (From egos, a mountain.) In Doscorides it is the Helenium, or a kind of elecampane growing upon mountains.

OREXIS (From ogegopus, to desire.)

Orexia. The appetite,
ORICIA. (From Oricus, a city of Epirus, near which it grows.) A species of fir or turpentine tree.

ORIENTALIA FOLIA. The leaves of

senna.

ORIGANUM. (From opos, a mountain, and yavee, to rejoice, so called because it grows upon the side of mountains.)

1 The name of a genus of plants in the Linnæan system. Class, Dydinamia. Or-

der, Gymnospermia

2 The charmacopecial name of Majorana mancarana. Originanum heracloeticum, from Heraclea, where the best was said to be produced. Zazarhendi herba. Wild marjorum. Origanum vulgare of Linnæus: spicis subrotunais paniculatis conglomeratis, bracteis calyce longioribus ovatis plant grows wild in many parts of Bri-It has an agrecable aromatic smell, approaching to that of marjoram, and a pungent taste, much resembling thyme, to which it is likewise thought to be more readily allied in its medicinal qualities, and therefore deemed to be emmenagogue, tonic, stomachic, &c. The dried leaves, used instead of tea, are said to be exceedingly grateful They are employed in medicated baths and fomentations.

ORIGANUM CRETICUM. See Dictamnus creticus.

ORIGANUM DICTAMNUS. The systematic name of the dittany of Crete. tamnus creticus.

ORIGANUM MAJORANA. The systematic name of sweet marjoram. See Marjo-

ORIGANUM SYRIACUM. The systematic name of the Syrian herb mastich. Marum.

ORIGANUM VULGARE, The systematic

581

name of the wild marjoram. See Origanum.

ORIS CONSTRUCTOR. See Orbicularis oris. ORLEANA TERRA. (Orleana, so named from the place where it grows.) The substance so called is a ceraceous mass, obtained from the seeds of the Bixa orleana of Linnaus. In Jamaica and warm climates it is considered as a useful remedy in dysentery, possessing adstringent and stomachic qualities.

ORNITHOGALUM MARITIMUM. (From oping, a bird, and yazz, milk, so called from the colour of its flowers, which are like the milk found in eggs.) A kind of wild onion.

See Scilla.

ORNITHOGLOSSUM. (From opic, a bird, and γλοςςα, a tongue, so called from its shape.) Bird's tongue. The seeds of the ash-tree, as sometimes so called.

ORNITHOLOGY. (From ορν, a bird, and λογος, a discourse) That part of natural

history which treats of birds.

ORNITHOPODIUM. (From ognica, a bird, and  $\pi sc$ , a foot; so called from the likeness of its pods to a bird's claw.) Bird's foot; scorpion wort.

ORNUS. (From orn, Heb.) 'The ash-

tree which affords manna.

ORDIANCHE. (From ogoGos, the wild pea, and ay 200, to suffocate; so called because it twines round the orobus, and destroys it.) The great tooth wort or hypocystis.

OROBRYCHIS. (From ogo60s, the woodpea, and βεοχο, to cat.) The same as oro-

bus.

OROBUS. (From spirlar, to eat.) 1. The name of a genus of plants in the Linmann system. Class, Diadelphia. Order, Decandria.

2. The pharmacopoial name of the ervum.

See Eroum

Oronus Tunknosus. The heath pea. The root of this plant is said to be nutritions. The Scotch Highlanders hold them in great esteem, and chew them like to-bacco.

OROSELINUM. See Oreoselinum.

ORPIMENT. Orpimentum. Native orpiment is found in yellow, brilliant, and, as it were, talcky masses, often mixed with realgar, and sometimes of a greenish colour. See Arsenic.

Orpine. See Faba crussa.

Oursilopealum (From ogos, the extremity, and πορη, the buttocks.) The extremity of the spine, which is terminated by the os coccygis.

ORRHOS. (From geo, to flow.) Serum, whey. The raphe, and the extremity of

the sacrum.

Orris, common. See Iris nostras.
Orris, Florentine. See Iris florentina.

Ournocolos. (From ορθος, straight, and καλον, a limb.) It is a species of stiff joint,

and is when it cannot be bended, but remains straight.

ORTHOPNOEA. (From ορθρος, erect, and στου, breathing) A very quick and laborious breathing, during which the person is obliged to be in an erect posture.

ORVALA. (Orvale, French.) A species

of clary or horminum.

ORVIETANUM is used for a medicine that resists poisons, from a mountebank of Orvieta in Italy, who first made himself famous by taking such things upon the stage, after doses of pretended poisons. Though some say its inventor was one H. F. Orvietanus, and that it is named after him.

ORYZA. (From orez, Arab.) 1. The

name of a genus of plants in the Linnæan system. Class, Triandria. Order, Digynia. 2. The name for rice, or the seeds of the Oryza sativa of Linnaus. Rice is the princip I food of the inhabitants in all parts of the East, where it is boiled and eaten, either alone or with their meat. Large quantities of it are annually sent into Europe, and is meets with a general esteem for family purposes. The people of Java have a method of making puddings of rice, which seems to be unknown here, but it is not difficult to put in practice, if it should merit attention. They take a conical carthen pot, which is open at the large end, and perforated all over: this they fill about half full with rice, and putting it into a larger earthen pot of the same shape, filled with boiling water, the rice in the first pot soon swells, and stops the perforations so as to keep out 'he water; by this method the rice is brought to a firm consistence, and forms a pudding, which is generally eaten with butter, oil, sugar, vinegar, and spices. The Indians eat stewed rice with good success against the bloody flux; and in most inflammatory dis orders they cure themselves with only a decoction of it. The spirituous liquor called arrack is made from this grain. Ricc grows naturally in moist places; and will not come to perfection, when cultivated, unless the ground be sometimes overflowed, or plentifully watered. grain is of a grey colour when first reaped; but the gr wers have a method of whitening it before it is sent to market manner of performing this, and beating it out in Egypt, is thus described by Hassel-quint: They have hollow iron cylindrical pestles, about an inch diameter, lifted by a wheel worked with oxen. A person its between the pestles, and, as they rise, pushes forward the rice, whilst another winnows and supplies fr sh parcels. Thus they continue working until it is entirely-free from chaff. Having in this manner cleaned it, they add one-thirtieth part of salt, and rub them both together, by which the grain acquires a whiteness; then it is

passed through a sieve, to separate the salt again from it. In the island of Ceylon they have a much more expeditious method of getting out the rice; for, in the field where it is reaped, they dig a round hole, with a level bottom, about a foot deep, and eight yards diameter, and fill it with bundles of corn. Having laid it properly, the women drive about half a dozen oxen continually round the pit; and thus they will tread out forty or fifty bushels a day. This is a very ancient method of treading out corn, and is still practised in Africa upon other sorts of grain.

ORYZA SATIVA. The systematic name of

the rice-plant. See Oryza.

OS. See Bone.

Os EXTERNUM. The entrance into the vagina. It is so named in opposition to the mouth of the womb, which is called the os internum, or os tincæ.

Os internum. Os tincæ, and amphideon, or amphideum. Galen calls it oscheon. The orifice or mouth of the womb.

Os LEONIS. The antirrhinum linaria.

OS TINCE. See Os internum.

OSCHEOCELE. (From ogxeor, the scrotum, and knan, a tumour) This term is sometimes given to a tumour of the scrotum, from an accumulation of water, (see Hydrocele); and sometimes to a scrotal hernia, (see Hernia.)

OSCHEON. OGXEOV. The scrotum. Galen

gives the name to the os uteri.

OSCHEOPHYMA. (From of xeov, the scrotum, and ouna, a tumour. (A swelling of the

Oscillation of Boerhaave. See Irritabi-

OSCITANS. (From oscito, to gape.) The yawning fever.

OSCITATIO. (From oscito, to gape.) Chasme. Oscedo. Yawning. Gaping.

OSCULATORIUS. (From osculo, to kiss; so called because the action of kissing is performed by it.) The sphincter muscle of the

OSCULUM. Dim. of os, a mouth.)

little mouth.

Osmund royal. See Osmunda regalis. OSMUNDA. (From Osmund, who first used it ) The name of a genus of plants in the Linnæin system. Class, Cryptogamia. Order, Filices.

OSMUNDA REGALIS. The systematic name of the osmund royal. Its root possesses ad-

stringent and styptic virtues.

OSPHYS. Ospus. The loins. OSSA SPONGIOSA.

The spongy bones are 'wo in number, and are called ossa spongiosa inferiora. The ethmoid bone has two turbinated portions, which are sometimes called the superior spongy bones. These bones, which, from their shape, are sometimes called ossa turbinata, have, by some anatomists, been described

as belonging to the ethmoid bone; and by others, as portions of the ossa palati. In young subjects, however, they are evidently distinct bones. They consist of a spongy lamella in each nostril. The convex surface of this lamella is turned towards the septum narium, and its concave part towards the maxillary bone, covering the opening of the lachrymal duct into the From their upper edge arise two processes: the posterior of these, which is the broadest, liangs as it were upon the edge of the antrum highmorianum; the anterior one joins the os unguis, and forms a part of the lachrymal duct. These bones are complete in the feetus. They are fined with the pituitary membrane; and, besides their connection with the ethnoid bone, are joined to the ossa maxillaria superiora. ossa palati, and ossa unguis. these ossa spongiosa inferiora, there are sometimes two others, situated lower down, one in each nostril. These are very properly considered as a production of the sides of the maxillary sanus turned downwards. In many subjects, likewise, we find other smaller bones, standing out into the nostrils, which, from their shape, might also deserve the name of turbinata, but they are uncertain in their size, situation, and number.

OSSICULA AUDITUS. The small bones of the internal ear are four in number, viz. the malleus, incus tapes, and os orbiculare; and are situated in the cavity of the tympanum. See Malleus, Incus, Stapes, and

Orbiculare os.

OSSIFICATION. (From os, a bone, and

facio, to make.) See Bone.

Ossifraga. (From os, a bone, and frango, to break.) A petrified root, called the bone-binder, from its supposed virtues in uniting fractured bones.

Ossifragus. See Osteocolla.

Ossivorus. (From os, a bone, and voro, to devour.) Applied to a species of tumour or ulcer, which destroys the bone.

OSTARGA. (From cortest, a bone, and appa, a laying hold of.) A forceps to take out

bones with.

(A porter, from ostium, a OSTARIUS. door; so called as being the passage into the bowels.) The lower orifice of the stomach.

OSTEITES. (From osesov, a bone.) The bone-binder. See Osteocolla.

OSTEOCOLLA. (From oster, a bone, and nonhaw, to glue.) Ossifraga. Holo-Osteites. Amosteus. Osteolithos. steus. Stelochites, glue bone, stone, or Bone-binder, A particular carbonate of lime, found in some parts of Germany, particularly in the Marché of Brandenburg, and in other countries. It is met with in loose sandy grounds, spreading from near the surface to a considerable depth, into a number of ramifications, like the roots of a tree; it is of whitish colour, soft whilst under the earth, it able when dry, rough on the surface, for the most part either hollow within, or filled with a solid wood, or with a powdery write matter. It was formerly celebrated for promoting the coalition of fractured bones, and the formation of callus; which virtues are not attributed to it in the present day.

OSTEOCOPUS. (From oster, a bone, and nortes, uneasiness.) A very violent fixed

pain in any part of the bone.

OSTEOGENICA. (From oster, a bone, and parvae, to beget.) Medicines which promote

the generation of a callus.

OSTEOGENY. (Osteogenia, from oseov, bone, and pavaz, generation.) growth of bones. Bones are either formed between membranes or in the substance of cartilages, and the bony deposition is effected by a determined action of arteries. The secretion of bone takes place in cartilage in the long bones, as those of the arm, leg, &c. and betwixt two layers of membrane, like the bones of the skull, where true cartilage is never seen. Often the bony matter is formed in distinct bags, and there it grows into form, as in the teeth; for each tooth is formed in its little bag, which by injection can be filled and covered with vessels. Any artery of the body can assume this action, and deposit bone, which is formed also where it should not he, in the tendons, and in the joints; in the great arteries, and in the valves, in the fiesh of the heart itself, or even in the soft and pulpy substance of the

All the bones in the fætus are merely cartilage before the time of birth; this cartilage is never hardened into bonc, but from the first it is an organized mass. It has its vessels, which are at first transparent, but which soon dilate; and whenever the red colour or the blood begins to appear in them, ossification very quickly succeeds, the arteries being so far enlarged as to carry the coarser parts of the blood. The first mark of ossification is an artery which is seen running into the centre of the jelly which is formed. Other arteries soon appear, and a net work of vessels is formed, and then a centre of ossification begins, stretching its rays according to the length of the bone, and then the cartillage begins to grow opaque, yellow, brittle; it will no longer bend, and a bony centre may easily be discovered. Other points of ossification are successively formed, preceded by the appearance of arteries. The ossification follows the vessels, and buries and hides those vessels by which it is formed. The vessels advance towards the ends of the bone, the whole body of the bone becomes opaque, and

either end; the heads are separated from the body of the bone by a thin cartilage, and the vessels of the centre, extending still towards the extremities of the bone, perforate the cartilage, pass into the head of the bone, and then its ossification also begins, and a small nucleus of ossification is formed in its centre. Thus the heads and the body are at first distinct bones, formed apart, joined by a cartilage, and not united till the age of fifteen or twenty years. Then the deposition of bone begins, and while the bone is laid by the arteries, the cartilage is conveyed away by the absorbing vessels; and while they convey away the superfluous cartilage, they model the bone into its due form, shape out its cavities, cancelli and holes, remove the thinner parts of the cartilage, and harden it into due consistence. The earth which constitutes the hardness of bone, and all its useful properties, is dead, inorganized, and lies in the interstices of bone, where it is made up of gelatinous matter, to give it consistence and strength, furnished with absorbents to keep it in health, and carry off its wasted parts; and pervaded by vessels to supply it with new matter. During all the process of ossification, the absorbents proportion their action to the stimulus which is applied to them; they carry away the serous fluid, when jelly is to take its place; they remove the jelly as the bone is laid; they continue removing the bony particles also, which (as in a circle,) the arteries continually renew; this renovation and change of parts goes on even in the hardest bones, so that after a bone is perfectly formed, its older particles are continually being removed, and new ones are deposited in their place. The bony particles are so deposited in the flat bones of the skull as to present a radiated structure, and the vacancies between the fibres which occasion this appearance are found, by injection, to be chiefly passages for blood-vessels. As the fortus increases in size, the osseous fibres increase in number, till a lamina is produced; and as the bone continues to grow, more lamina are added, till the more solid part of a bone is formed. The ossification which begins in cartilage is considerably later than that which has its origin between membranes. The generality of bones are incomplete until the age of puberty, or between the fifteenth and twentieth year, and in some few instances not until a later period: the small bones of the ear however are completely formed at birth.

OSTEOGRAPHY. (From ος εεν, a bone, and γραφα, to describe.) The description of the bones. See *Bone*.

OSTEOLITHOS. (From ossev, a bone, and

OSTEOLOGY. (From oseen, a bone, and hopes, a discourse.) The doctrine of the bones. See Bone.

OSTIOLA. (Dim. of ostium, a door.) The

valves or gates of the heart.

OSTREUM. (From ospanor, a shell.) The oyster. The shell of this fish is occasionally used medicinally; its virtues are similar to those of the carbonate of lime. See Creta.

OSTRITIUM. (Blanchard calls it a corruption from laserpitium.) Imperatoria, or masterwort.

OSTRUTHIUM. Laserpitium. See Imperatoria.

OSTRIS. Cassia poetica Lobellii. Cassia latinorum. Cassia lignea monspeliensium. Cassia monspeliensium. Poet's rosemary. The whole shrub is astringent. It grows in the southern parts of Europe.

OSTALGIA. (From 85, the ear, and anyos,

pain.) The ear-ache.

OTENCHYTES (From ωτος, the genitive of ους, an ear, and εγχευα, to pour in.) A syringe for the ears.

OTHONNA. (From obown, lint; so called from the softness of its leaves.) A species of c-landine.

OTICA. (From 85, the ear) Medicines ag inst diseases of the ear

OTITES. (From 85, the ear.) An epithet of the little finger, because it is commonly

of the little finger, because it is commonly made use of in scratching the ear.

OTITIS. (From ss, the ear) Inflammation of the internal ear. It is known by pyrexia, and an excruciating and throbbing pain in the internal ear, that is sometimes attended with delirium.

OTOPLATOS. (From 85, the ear.) A stink-

ing utcer helind the ears.

OTOPYOSIS. (From 85, the ear, and muov, pus.) A purulent discharge from the

OTORRHÆA. (From 85, the ear, and gsw, o flow.) A discharge of blood or matter from the ear.

OVALE FORAMEN. (See Foramen

ovale.)

OVARIUM. (Dim. of ovum, an egg.) The ovaria are two flat oval bodies, about one inch in length, and rather more than half in breadth and thickness, suspended in the broad ligaments, about the distance of one inch from the uterus behind, and a little below, the Fallopian tubes. To the ovaria, according to the idea of their structure entertained by different anatomists, various uses have been assigned, or the purpose they answer has been differently explained. Some have supposed that their texture was glandular, and that they secreted a fluid equivalent to, and similar to, the male semen; but others, who have examined them with more care, assert that they are ovaria in the literal acceptation of the term, and include a number of vesicles,

or ova, to the amount of twenty-two, of different sizes, joined to the internal surface of the ovaria by cellular threads or pedicles; and that they contain a fluid which has the appearance of thin lymph. These vesicles are, in fact, to be seen in the healthy ovaria of every young woman. They differ very much in their number in different ovaria, but are very seldom so numerous as has just been stated. All have agreed, that the ovaria prepare whatever the female supplies towards the formation of the fœtus; and this is proved by the operation of spaying, which consists in the extirpation of the ovaria, after which the animal not only loses the power of conceiving, but desire is for ever extinguished. The outer coat of the ovaria. together with that of the uterus, is given by the peritonæum; and whenever an ovum is passed into the Fallopian tube, a fissure is observed at the part through which it is supposed to have been transferred. These fissures healing, leave small longitudinal cicatrices on the surface, which are said to enable us to determine, whenever the ovarium is examined, the number of times a woman has conceived. The corpora lutea are oblong glandular bodies of a yellowish colour, found in the ovaria of all animals when pregnant, and, according to some, when they are salacious. They are said to be calyces, from which the impregnated ovum has dropped; and their number is always in proportion to the number of conceptions found in the uterus. They are largest and most conspicuous in the early state of pregnancy, and remain for some time after delivery, when they gradually fade and wither till they disappear. The corpora lutea are very vascular, except at their centre, which is whitish; and in the middle of the white part is a small cavity, from which the impregnated ovum is thought to have immediately proceeded. The ovaria are the seat of a particular kind of dropsy, which most commonly happens to women at the time of the final cessation of the menses, though not unfrequently at a more early period of life. It is of the encysted kind, the fluid being sometimes limpid and thin, and at others discoloured and gelatinous. In some cases it has been found to contain one cyst, often in several, and in others the whole tumefaction has been composed of hydatids not larger than grapes. The ovaria are also subject, especially a short time after delivery, to inflammation, terminating in suppuration, and to schirrhous and cancerous diseases, with considerable enlargement. In the former state, they generally adhere to some adjoining part, as the uterus, rectum, the bladder, or the external integuments, and the matter is discharged from

the vagina by stool, by urine, or by any external abscess of the integuments of the abdomen.

OVIDUCT. (Oviductus, from ovum, an egg, and ductus, a canal.) The Fallopian tube, or canal, which runs from the ovary to the bottom of the womb.

OVIPAROUS. (From ovum, an egg, and pario, to bring forth.) Animals which exclude their young in the egg, which are afterwards hatched

OVORUM TESTAL. Egg-shells. A testaceous absorbent.

OVUM. See Egg.

OVUM PHILOSOPHICUM. Ovum chymicum. A

glass body, round like an egg.

OXALATS. Oxalas. Salts formed by the combination of the oxalic acid with different bases; thus, oxalat of ammonia,

OXALIC ACID. Acidum oxalicum. Salt of sorrel. Acid of sugar. This acid is obtained by evaporating the fresh juice of sorrel almost to the consistence of honey, when it is to be poured into a glass vessel with a narrow neck, and covered with a stratum of the oil of olives. After some weeks the sides of the bottle are invested with a crust, which is the salt of sorrel, or oxalis potassa acidulus. The salt of sorrel is then to be dissolved in boiling water, and a small quantity of the nitrate of barytes added to it, when the barytes will unite with the oxalic acid, and the potash with the nitric acid. The oxalat of barytes, which is precipitated, is then to be decompounded by digestion with sulphuric acid, by which means the oxalic acid is let loose. Formerly this acid was considered as different from that of sugar, but it is now proved by experiments to be the same in all its properties.

OXALIS. (From oğue, sharp; so called from the sharpness of its juice.) The name of a genus of plants in the Linnæan system. Class, Decandria. Order, Pentagynia. Woodsorrel.

OYALIS ACETOCELLA. (Dim. of acetosa.) The systematic name of the wood-sorrel. See Lujula.

(From egue, sharp, and axe, OXALME. salt.) A mixture of vinegar and salt.

See Rellis major. Ox-cye-daisy O.r's tongue. See Picris echioides.

OXYCANTHA GADENT. (From ofoc, sharp, and axarba, a thorn; so called from the acidity of its fruit.) The barberry. See Berberia.

Oxycennus. (From ogo, acutely, and usses, a cedar; so called from the sharp termination of its leaves.) A kind of cedar. Spanish juniper, a species of juniperus.

Oxycoccos. (From ogue, acid, and nonxoc, a berry, so named from its acidity.) Vaccinia palustris. Vitis ideza palustris. Moor-berry. The cranberry. The berries of the Vaccinium oxycoccos of Linnæus are so termed in some pharmacopæias. They are about the size of our haws, and are pleasantly acid, with which intention they are used medicinally in Sweden. In this country they are mostly preserved and made into tarts.

OXYCRATUM. (From ogus, acid, and xegave vuu, to mix.) Oxycrates. Vinegar mixed with such a portion of water as is required, and rendered still milder by the addition of a little honey.

OXYCROCEUM EMPLASTRUM. (From ozus, acid, and xponos, crocus, saffron.) A plaster in which there is much saffron, but no vinegar necessary, unless in dissolving some gums.

OXYD. Oxyd. Oxide. Oxyde. Oxydum. A substance formed by the union of oxygen with a basis: thus, axyd of iron, oxyd of copper, &c.

Oxyd of carbon, gazeous. See. Carbon,

gazeous oxyd of.
OXYDATION. The operation by which a substance is made to combine with oxy-

OXYDERCICA. (From ogue, acute, and Seena, to see.) Medicines which sharpen the sight.

OXYDUM. (So called from oxygen, which enters into its composition.) See

OXYDUM ANTIMONII. Oxyd of antimony. This is the calx antimonii, the crocos antimonii lotus, and the antimonium diaphoreticum, of old pharmacopæias. It is made thus: "Take of sulphuret of antimony, powdcred, two ounces, muriatic acid, eleven fluid ounces, nitric acid, one fluid-ounce. The acids being mixed together in a glass vessel, add the antimony gradually thereto, and digest them in a boiling heat for an hour, then strain the solution and pour it into a gallon of water, in which two ounces of the subcarbonate of potash have been previously dissolved; wash the precipitated powder by repeated effusions of water until all the acid is washed away, then dry it upon bibulous paper." This preparation possesses diaphoretic virtues, and is given in the dose of from three grains to ten.

OXYDUM ARSENICI ALBUM. See Arsenious acid.

OXYDUM CUPRI VIRIDE ACETATUM. Verdigris.

OXYDUM FERRI LUTEUM. See Ferri car. bonas.

OXYMURIAS HYDRARGYRI. Hydrargyrus muriatus. Oxymuriat of mercury. Take of purified mercury by weight two pounds, sulphuric acid by weight thirty ounces, dried muriate of soda four pounds. Boil the mercury with the sulphuric acid in a glass vessel until the sulphate of mercury shall be left dry. Rub this, when it 4 F \*

is cold, with the muriate of soda in an earthen-ware mortar; then sublime it in a glass cucurbit, increasing the heat gradually.

An extremely acrid and violently poi-

sonous preparation.

Given internally in small doses properly diluted, and never in the form of pill, it possesses oxygenating, antisyphilitical, and alterative virtues. Externally applied, in form of lotion, it facilitates the healing of venereal sores, and curcs the itch. gargles for venereal ulcers in the throat the oxymuriat of mercury gr. iii. or iv., barley decoction lbj., honey of roses 3jj., proves very serviceable; also in cases of tetters, from gr. v. to gr. x. to water Hoj.; and for films and ulcerations of the cornea, gr. i. to

water Ziv.

Mr. Pearson remarks that when the sublimate is given to cure the primary symptoms of syphilis, it will sometimes succeed; more especially, when it produces a considerable degree of soreness of the gums, and the common specific effects of mercury in the animal system. But it will often fail of removing even a recent chancre; and where that symptom has vanished during the administration of corrosive sublimate, I have known, says he, a three months' course of that medicine fail of securing the patient from a constitutional affection. The result of my observations is, that simple mercury, calomel or calcined mercury, arc preparations more to be confided in for the cure of primary symptoms, than corrosive sublimate. The latter will often check the progress of secondary symptoms very conveniently, and I think it is peculiarly efficacious in relieving venercal pains, in healing ulcers of the throat, and in promoting the desquamation of eruptions. Yet even in these cases it never confers permanent benefit; for new symptoms will appear during the use of it; and on many occasions it will fail of affording the least advantage to the patient from first to last. I do, sometimes, indeed, employ this preparation in venereal cases; but it is either at the beginning of a mercurial course, to bring the constitution under the influence of mercury at an early period, or during a course of inunction, with the intention of increasing the action of simple mercury. I sometimes also prescribe it after the conclusion of a course of friction, to support the mercurial influence in the habit, in order to guard against the danger of a relapsc. But on no occasion whatever do I think it safe to confide in this preparation singly and uncombined, for the cure of any truly venereal symptom.

OXYDUM HYDRARGYRI CINEREUM. Grey oxyd of mercury. "Take of submuriate of mercury, an ounce; lime-water, a gallon." Boil the submuriate of mercury in the lime-water, constantly stirring, until a grey oxyd of mercury is separated. Wash this with distilled water, and then dry it.

The dose from gr. ii. to x.

OXYDUM HYDRARGYRI NIGRUM. The black oxyd of mercury has received several names. Ethops per se. Pulvis mercurialis cinereus. Nercurius cinereus. Turpethum nigrum. Mercurius pracipitatus ni. ger. There are four preparations of it in high estimation:

One made by rubbing mercury with mucilage of gum arabic. Plenk, of Vienna, has written a treatise on the superior efficacy of this medicine. It is very troublesome to make; and does not appear to possess more virtues than some other mercurial

preparations.

Another made by triturating equal parts

of sugar and mercury together.

The third, composed of honey or liquorice and hydrargyrus purificatus.

The fourth is the blue mercurial ointment. All these preparations possess anthelmintic, antisyphilitic, alterative, sialagogue, and deobstruent virtues, and are exhibited in the cure of worms, syphilis, amenorrhæa, diseases of the skin, chronic diseases, ob-

structions of the viscera, &c.

OXYDUM HYDRARGYRI RUBRUM. Hydrargyrus calcinatus. Red oxyd of mer-cury. "Take of purified mercury by weight a pound." Pour the mercury into a glass mattrass, with a very narrow mouth and broad bottom. Apply a heat of 600° to this vessel, without stopping it, until the mercury has changed into red scales; then reduce these to a very fine powder.

The whole process may probably require

an exposure of six weeks.

This preparation of mercury is given with great advantage in the cure of syphil-Its action, however, is such, when given alone, on the bowels, as to require the addition of opium, which totally prevents it. It is also given in conjunction with opium and camphire, as a diaphoretic, in chronic pains and diseases of long continuance.

It is given as an alterative and diaphoretic from gr. ss ad. ii. every night, joined with camphor and opium, cach gr. onefourth or one-half. It is violently emetic and cathartic in gr. iv. to gr. v.

OXYDUM PLUMBI ALBUM. See Subcarbonas

OXYDUM PLUMBI HUBRUM. See Lead. Oxydum plumbi semivitreum. See Lithargyrus.

OXYDUM STIBII ALBUM. See Oxydum anti-

OXYDUM STIBIL SEMIVITHEUM. treous oxyd of antimony. It was formerly called Vitrum antimonii, and consists of an oxyd of antimony with a little sulphur; it is employed to make antimonial wine.

OXYDUM STIBIL SULPRURATUM. is an oxid of antimony with sulphur, and was formerly called Hepar antimonii. Crocus metallorum. Crocus antimonii. It was formerly exhibited in the cure of fevers and atonic diseases of the lungs. Its principal use now is in preparing other medicines.

OXYDUM ZINCI SUBLIMATUM.

oxydum.

OXYDUM ZINCI. See Zinci Oxydum. Oxyganum. (From ogus, acid, and 22-50, garum.) A composition of garum and

vinegar.

OXYGEN. (Oxygenium; from cgus, acid, and pievouxi, to generate; because it is the generator of acidity.) This substance, although existing sometimes in a solid and sometimes in an aëriform state, is never distinctly perceptible to the human senses, but in combination.

We know it only in its combination, by its effects. Nature never presents it solitary; chymists do not know how to insulate It is a principle which was long unknown. It is absorbable by combustible bodies, and converts them into acids. It is an indispensable condition of combustion, uniting itself always to bodies which burn, augmenting their weight, and changing their properties. It may be disengaged in the state of oxygen gas, from burnt bodies, by a joint accumulation of caloric and light. It is highly necessary for the respiration of animals. It exists universally dispersed through nature, and is a constituent part of atmospheric air, of water, of acids, and of all bodies of the animal and vegetable kingdoms.

One of the most remarkable combinations into which it is capable of entering, is that which it forms with light and caloric. The nature of that mysterious union has not been ascertained, but it is certain that, in that state, it constitutes the gazeous

fluid called OXYGEN GAS.

Properties of Oxygen Gas.—Oxygen gas is an elastic invisible fluid, like common air, capable of indefinite expansion and compression. It has neither taste or odour, nor does it show any traces of an acid. Its specific gravity, as determined by Kirwan, is 0.00135, that of water being 1.0000; it is, therefore, 740 times lighter than the same bulk of water. Its weight is to atmospheric air as 1103 to 1000 One hundred and sixteen cubic inches of oxygen gas weigh 39.38 grains. It is not absorbed by water, but entirely absorbable by combustible bodies, which, at the same time, disengage its caloric and light, producing in consequence a strong heat and flame. rekindles almost extinct combustible bodies. It is indispensable to respiration, and is the cause of animal heat. It hastens germination. It combines with every combustible body, with all the metals, and with the greater number of vegetable and animal substances. It is considered as the cause of acidity; and from this last property is derived the name oxygen, a word denoting the origin of acidity.

The act of its combining with bodies is called oxydation, or oxygenation; and the bodies with which it is combined are called

oxyds.

Oxygen gas is the chief basis of the

pneumatic doctrine of chymistry.

Methods of obtaining Oxygen Gas .- We are at present acquainted with a great number of bodies, from which we may, by art, produce oxygen gas. It is most amply obtained from the oxyds of manganese, or mcrcury; from nitrate of potash; from the green leaves of vegetables, and from oxygenated muriate of potash, or soda. Besides these, there are a great many other substances, from which oxygen gas may be procured.

1. In order to procure oxygen gas in a state of great purity, pure oxygenated muriate of potash, or soda, must be made use With this view, put some of the salt into a small earthen or glass retort, the neek of which is placed under the shelf of the pncumatic trough, filled with water; and heat the retort by means of a lamp. The salt will begin to melt, and oxygen gas will be obtained in abundance, and of great purity, which may be collected and preserved over water.

Explanation .- Oxygenated muriate of potash consists of oxygenated muriatic acid and potash; at an elevated temperature, a decomposition of the oxygenated muriatic acid takes place; its oxygen unites to the caloric, and forms oxygen gas. The oxygenated acid becomes the etore converted into simple muriatic acid, which remains in the retort united to the potash, in the form of muriate of potash.

Oxygen gas may likewise be obtained from the green leaves of vegetables.

For this purpose fill a bell-glass with water, introduce fresh-gathered green leaves under it, and place the bell, or receiver, inverted, in a vessel containing the same fluid; expose the apparatus to the rays of the sun, and very pure oxygen gass will be liberated.

The emission of oxygen gas is proportioned to the vigour of the plant and the vivacity of the light; the quantity differs in different plants and under different conditions

Explanation.-It is an established fact, that plants decompose water, and probably carbonic acid, which serve for their nourishment; they absorb the hydrogen and carbon of these fluids, disengaging a part of the oxygen in a state of purity. Light, however, favours this decomposition greatly; it seems to serve for melting the oxygen, and thus forms it into oxygen gas; in proportion as it becomes disengaged, the hydrogen becomes fixed in the vegetable, and combines partly with the carbon and partly with the oxygen, to form the oil, &c. of the vegetable.

3. Nitrate of potash is another substance frequently made use of for obtaining oxygen gas, in the following manner:

Take any quantity of this salt, introduce it into a coated earthen or glass retort, and fit to it a tube, which must be plunged into the pneumatic trough, under the receiver filled with water. When the apparatus has been properly adjusted, heat the retort gradually, till it becomes red hot; the oxygen gas will then be disengaged rapidly. The gas obtained in this way is also

very pure, especially if the last portion be

kept separate.

Explanation.—Nitrate of potash consists of nitric acid and potash. Nitric acid consists again of oxygen and nitrogen. On exposing the salt to ignition, a partial decomposition of the acid takes place; the greatest part of the oxygen of the nitric acid unites to caloric, and appears under the form of oxygen gas. The other part remains attached to the potash in the state of nitrous acid. The residue in the retort is, therefore, nitrite of potash, if the process has been carefully conducted.

Remark.—If too much heat be applied, particularly towards the end of the process, a total decomposition of the nitric acid takes place; the oxygen gas, in that case, will therefore be mingled with nitrogen gas. The weight of the two gases, when collected, will be found to correspond very exactly with the weight of the acid which had been decomposed. The residue then

left in the retort is potash.

4. Black oxyd of manganese, however, is generally made use of for obtaining oxygen gas, on account of its cheapness. This native oxyd is reduced to a coarse powder; a stone, or rather an iron retort, is then charged with it and heated. As soon as the retort becomes ignited, oxygen gas

is obtained plentifully.

Explanation.—Black oxyd of manganese is the metal called manganese fully saturated with oxygen, together with many earthy impurities; on applying heat, part of the solid oxygen quits the metal and unites to caloric, in order to form oxygen gas, the remainder of the oxygen remains united to the metal with a forcible affinity; the metal, therefore, re-approaches to the metallic state, or is found in the state of a grey oxyd of manganese.

One pound of the best manganese yields upwards of 1400 cubic inches of oxygen

gas, nearly pure. If sulphuric acid be previously added to the manganese, the gas is produced by a less heat, and in a larger quantity; a glass retort may then be used, and the heat of a lamp is sufficient.

5. Red oxyd of mercury yields oxygen gas in a manner similar to that of manga-

iese.

Explanation.—This oxyd consists likewise of solid oxygen and mercury, the combination of which takes place on exposing mercury to a heat of about 610° Fahr. At this degree it attracts oxygen, and becomes converted into an oxyd; but if the temperature be increased to about 1000°, the attraction of oxygen is changed. The oxygen then attracts caloric stronger than it did the mercury; it therefore abandons it and forms oxygen gass. The mercury then re-appears in its metallic state.

6. Red oxyd of lead yields oxygen gas

on the same principle.

OXYGENATED MURIATIC ACID This gas possesses an uncommonly pungent and suffocating odour. It is absolutely and in every respect non-respirable; animals immersed in it die instantly. It is absorbable by water, and forms with it what is called liquid oxygenated muriatic acid. When water is saturated with it, the compound crystallizes at low temperatures. Oxygenated muriatic acid gas is not invisible, but has a yellow-greenish colour. It is capable of maintaining and exciting com-bustion in many cases. Phosphorus, charcoal, red sulphuret of mercury, sulphuret of antimony, bismuth, iron, zinc, copper, gold, arsenic, cobalt, tin, lead, and several other combustible bodies, take fire spontaneously when introduced into it. It is heavier than atmospheric air. It weakens and reddens the flame of a taper, but does not extinguish it. It decomposes ammonaithickens fat oils. It detonates with hydrogen gas. Nitrous gas immediately produces a cloud of reddish vapour with it. It is likewise decomposed by sulphurated, phosphorated, and carbonated hydrogen gases. It is not altered by exposure to light, and passes unaltered through an ignited porcelain tube It discolours stuffs, and totally destroys most of the vegetable colours, rendering them white. It also bleaches yellow wax, &c.

This gas may be obtained in several

ways.

1. Take one part of the native oxyd of manganese, one of red precipitate of mercury, or red lead, put it into a glass retort, and add four parts of concentrated muriatic acid. This, on distillation, affords a quantity of yellow aëriform fluid, which is oxygenated muriatic acid gas, and by agitating it with water, it combines and forms oxygenated muriatic acid.

It may also be obtained without the red mercurial precipitate, or red lead, thus:

2. Put into a retort one part of powdered black oxyd of manganese, three or four of concentrated muriatic acid, connect the retort with the pneumatic trough, and receive the gas over water in the usual manner. When no more gas is liberated, apply the heat of a lamp, and gas will be produced abundantly, which may be kept in bottles with ground glass stoppers.

The oxyd of manganese yields up in this process part of its oxygen to part of the muriatic acid, which becomes converted into oxygenated muriatic acid gas; the oxyd of manganese being thus partly deoxydated, is dissolved in the remaining quantity of the muriatic acid, which remains behind in the retort as muriate of

manganese.

The retort containing the mixture should not be filled above one-third, for the mixture, on the application of heat, swells and is otherwise very apt to be forced over into

the neck of the retort.

3. Oxygenated muriatic acid gas may likewise be obtained in an indirect manner, by decomposing muriate of soda in contact with black oxyd of manganese. For that purpose mix eight parts, by weight, of muriate of soda with three of powdered oxyd of manganese, put the mixture into a tubulated retort, and pour upon it gradually four parts of sulpluric acid, diluted previously with three of water, and which has been suffered to cool after dilution. On applying a gentle heat, gas will be produced as before.

In this operation the sulphuric acid acts on the muriate of soda, to the base of which it unites; the muriatic acid formed by this union attacks the oxyd of manganese; one part of it combines with the oxygen, and another with the oxyd brought nearer to the metallic state, and the result is sulphat of soda and muriate of manganese, which remain in the distilling vessel; and oxygenated muriatic acid, which passes in the state of gas at common temperatures.

In preparing this gas great care should be taken that it does not escape into the apartment in any considerable quantity; as it acts violently on the pituitous membrane, occasions a defluxion of the brain, blunts the senses of smell and taste, produces head-ach, and proves extremely injurious to health.

Pelletier fell a sacrifice in attempting to breathe it; a consumption was the conse-

quence, which proved fatal.

Liquid ammonia is the remedy best calculated to check its effects, when accidentally set at liberty in places where it is prepared.

The water which adheres to the inner

side of the vessel filled with oxygenated muriatic acid gas crystallizes in the form of yellow spangles, if the temperature is near the freezing point. If a considerable quantity of gas be thus condensed, care must be taken to keep it at a low temperature; for as soon as the temperature is raised, it expands, and endangers the bursting of the vessel. When absorbed by water it forms liquid

OXYGENATED MURIATIC ACID.-This acid is of a greenish yellow colour. It has a styptic bitter taste, and a very suffocating odour. Instead of reddening blue vegetable colours, it has the remarkable property of rendering them white. high temperatures, we en light is excluded, phosphorus remains unaltered in liquid oxygenated muriatic acid; but if light be admitted, the colour of the acid gradually disappears, and the phosphorus is converted into phosphoric acid. It thickens oils and animal fats, and renders them less disposed to combine with alkalies. Its action upon metals presents phenomena extremely curious and important; the oxygen of the acid unites with the metal, and the produced oxyd is afterwards dissolved by the de-oxydated acid.

Method of obtaining Oxygenated Muriatic Acid .- Put into a tubulated retort, supported over a lamp, one part of black oxyd of manganese reduced to a gross powder, and pour over it three parts of concentrated inuriatic acid, recline the retort in such a manner that the fluid which rises up into its neck, may easily run back again into the body, and apply a receiver with a little distilled water in it; the receiver must be luted to the retort by a fillet of When the offervescence, which instantly takes place on the affusion of the acid, ceases, apply a gentle heat. Oxygenated muriatic acid gas will be evolved, and the receiver become filled with yellow vapours, which are absorbed by the water. When the water has acquired a yellowishgreen colour, the receiver may be removed, and another one applied till no more gas is extricated. The process may be more clegantly conducted, by joining the apparatus of Burkitt or Pepys to the distillatory vessel. The common muriatic acid which may arise is condensed in the first bottle, and the oxygenated muriatic acid gas unites to the water in the second. third, &c.

The union of oxygenated muriatic acid with different bases forms salts, known by the name of oxygenated muriates.

Oxygercum. (From εξυς, acid, and γλυκυς, sweet.) Honey mixed with vinegar. An oxymel.

ΟΧΥΙΑΡΑΤΗΙΙΜ. (From οξυς, acid, and λαταθον, the dock; so named from its acidity.) Lapathum acutum. Rumex acutus

of Linnaus. Sharp-pointed dock. Humer foribus hermaphroditis; valvula dentatis graniferis, folis cordato oblongis acuminatis. The decoction of the root of this plant is used in Germany to curé the itch; and it appears to have been used in the time of Dissocrides, in the cure of leprous and imperingenous affections, both alone and boiled with vinegar.

ONYMEL. (From εξως, acid, and μελι, honey.) Apomeli. Adipson. Honey and vinegar boiled to a sirup. See Mel acetatum.

OXYMEL ERUGINIS. See Linimentum

aruginia,

OXYMEL COLUMNIC. Oxymel of meadow saffron is an acrid medicine, but is nevertheless employed, for its diuretic virtues, in dropsies.

OXYMEL SCILLE. A very useful expec-

torant.

OXIMPRHINE. (From Eys, acute, and uvggun, the myrtle; so called from its resemblance to myrtle, and its pointed leaves.)

Oxymprsine. Wild myrtle.

OXIMERSINE. See Oxymyrrhine.

OXINITRUM (From egus, acid, and m-

of vinegar and nitre.

OXYOPIA. (From egus, acute, and equs, vision.) The faculty of seeing more acutely than usual. Thus there have been instances known of persons who could see the stars in the day-time. The proximate cause is a preternatural sensibility of the retina. It has been known to precede the gutta serena; and it has been asserted that prisoners, who have been long detained in darkness, have learned to read and write in darkened places.

Oxypalegnasia (From εξυς, acute, and φλερα, to burn.) An acute inflamma-

م ومدين المدينة

OXYPHENICON. (From egus, acid, and come, the tamarind; a native of Phonicia.) See Tamarindus.

OXYPHONIA (From ozos, sharp, and earn, the voice.) The same as Paraphonia Clangens. It is a howling.

Oxyregma. (From εξυς, acid, and εξυς, α, to break wind.) An acid eructation. Oxyrerhodinos. (From εξυς, acid, and

OXYRRHODINON. (From ogus, acid, and godnor, oil of roses.) A composition of the oil of roses and vinegar.

OXTRACTHARUM. (From Egus, acid, and oxax/agos, sugar.) A composition of vinegar and sugar.

OXYSAL PLAPHORETICUM. A preparation of Angelus Sala. It is a fixed salt, loaded with more acid than is necessary to saturate it. The salt of Juniper is of this kind.

ΟΧΥΤΟCA. (From οξυς, quick, and τικτα, to bring forth.) Medicines which promote delivery.

OXYTRIPHYLLUM. (From οξυς, acid, and τg/2υλλος, trefoil; so named from its acidity.) Wood-sorrel.

Oyster. See Ostreum. Oyster.shell. See Ostreum.

OZŒNA. (From ośn, a stench.) An ulcer situated in the nose, discharging a fætid purulent matter, and sometimes accompanied with caries of the bones. Some authors have signified by the term, an ill. conditioned ulcer in the antrum. The first meaning is the original one. The disease is described as coming on with a trifling tumefaction and redness about the ala nasi. accompanied with a discharge of mucus, with which the nostril becomes obstructed. The matter gradually assumes the appearance of pus, is most copious in the morning, and is sometimes attended with sneezing, and a little bleeding. The ulceration occasionally extends round the ala nasi to the cheek, but seldom far from the nose, the ala of which also it rarely destroys. The ozena is often connected with scrophulous and venereal complaints. In the latter cases, portions of the ossa spongiosa often come away. After the complete cure of all venereal complaints, an exfoliating dead piece of bone will often keep up symptoms similar to those of the ozena, until it is detached. Mr. Pearson remarks, that the ozena frequently occurs as a symptom of the cachexia syphyloidea. It may perforate the septum nasi, destroy the ossa spongiosa, and even the ossa nasi. Such mischief is now more frequently the effect of the cachexia syphyloidea, than of lues venerea. The ozona must not be confounded with abscesses in the upper jaw-

OZYNUM. (From εξα, to smell; so called from its fragrance.) Sweet basil.

P.

P. A contraction of pugillus, a pugil, or eighth part of a handful, and sometimes a contraction of partes, parts.

P. Æ. A contraction of partes aquales. P. P. A contraction of pulvis pairum, Jesuit's powder.

PABULUM. (From pasco, to feed.)
Food, aliment. The animal heat and animal spirits are called pabulum vitx, the food of life.

Pacchionian glands. See Glandulæ Pacchionæ.

591

PACHENTICA. (From @1214, to incres-Medicines which incrassate or thicken the fluids.

PACHYS PAZU, thick. The name of a disorder described by Hippocrates, but not

known by us.

Padus. The wild cluster cherry, or bird's cherry. The Printus padus of Linnæus. The bark and berries of this shrub are used medicinally. The former, when taken from the tree, has a fragrant smell, and a bitter, subastringent taste, somewhat similar to that of bitter almonds. Made into a decoction, it cures intermittents, and it has been recommended in the cure of several forms of syphylis. The latter are said to cure the dysentery.

P.EDANCHONE. (From was, a child, and αγχω, to strangulate.) A species of quinsy

common among children.

PEDARTHROCACE. (From was, a boy, aggeor, a joint, and xaxor, an evil.) The joint evil. Severinus calls the Spina Ventora by this name, as also doth Dr Cullen. By some this name is used to express a sort of anasarca.

PÆONIA. (From Peon, who first applied it to medicinal purposes.) 1. The name of a genus of plants in the Linnzan system. Class, Polyandria. Order, Digynia.

2. The pharmacopæial name of the common peony. Male and female peony. This plant, Paonia officinalis of Linnans:-folis oblongis, has long been considered as a powerful medicine; and, till the late revision by the London College, it had a place in the catalogue of the Materia Medica; in which the two common varieties of this plant arc indiscriminately directed for use: and, on the authority of G. Bauhin, improperly distinguished into male and female

peony.

The roots and seeds of peony have, when fresh, a faint, unpleasant smell, somewhat of the narcotic kind, and a mucilaginous, subacrid taste, with a slight degree of bitterness and adstringency. In drying, they lose their smell and part of their taste. Extracts made from them by water are almost insipid, as well as inodorous; but extracts made by rectified spirits are manifestly bitterish, and considerably adstringent. The flowers have rather more smell than any of the other parts of the plant, and a rough, sweetish taste, which they impart, together with their colour, both to water and spirit.

The roots, flowers, and seeds of peony, have been esteemed, in the character of an anodyne and corroborant, but more especially the roots; which, since the days of Galen, have been very commonly employed as a remedy for the epilepsy. For this purpose, it was usual to cut the root into thin slices, which were to be attached to a string,

and suspended about the neck as an an ulet; if this failed of success, the patient was to have recourse to the internal use of this root, which Willis directs to be given in the form of a powder, and in the quantity of a drachm, two or three times a-day, by which, as we are informed, both infants and adults were cured of this disease. Other authors recommended the expressed juice to be given in wine, and sweetened with sugar, as the most effectual way of administering this plant. Many writers, however, especially in modern times, from repeated trials of the peony in epileptic cases, have found it of no use whatever; though Professor Home, who gave the radix pagnix to two epileptics at the Edinburgh infirmary, declares that one received a temporary advantage from its usc. Of the good effects of this plant, in other disorders, we find no instances recorded.

PAONIA OFFICINALIS. The systematic name of the common paony. Sec Paonia.

Paigil. See Primula veris. PAIN. Dolor. Any unpleasant sensation, or irritation.

Painter's colic. See Colica pictonum.

Palate. See Palatum.

PALATE BONE. (Os palati; from pale, to hedge in; because it is staked in, as it were, by the teeth.) These two bones are of very irregular figure. They are placed between the ossa maxilaria superiora and the os splienoides, at the back part of the roof of the mouth, and extend from thence to the bottom of the orbit. Each of these bones may be divided into four parts, viz. the inferior, or square portion, the pterygold process, the nasal lamella, and orbitar process. The first of these, or the square part of the bone, helps to form the palate of the mouth. The upper part of its internal edge rises into a spine, which makes part of the septum narium. The pterygoid process, which is smaller above than below, is so named from its being united with the pterygoid processes of the sphenoid bone, with which it helps to form the pterygoid fossæ. It is separated from the square part of the bone, and from the nasal iamella. by an oblique fossa, which, applied to such another in the os maxillare, forms a passage for a branch of the filth pair of nerves. The nasal lamella is nothing more than a very thin bony plate, which arises from the upper side of the external edge of the square part of the bone. Its inner surface is concave, and furnished with a ridge, which supports the back part of the os spongiosum inferius. Externally, it is convex, and firmly united to the maxillary bone. The orbitar process is more irregular than any other part of the bone. It has a smooth surface, where it helps to form the orbit; and, when viewed in its place, we see it

contiguous to that part of the orbit which is formed by the os maxillare, and appearing as a small triangle at the inner extremity of the orbitar process of this last men-This fourth part of the os tioned bone palati likewise helps to form the zygomastic fossa on each side, and there its surface is Between this orbitar process concave. and the sphenoid bone, a hole is formed, through which an artery, vein, and nerve, are transmitted to the nostrils. The ossa palati are complete in the fœtus. They are joined to the ossa maxillaria superiora, os sphenoides, os ethmoides, ossa spongiosa inferiora, and vomer

PALATI CIRCUMPLEXUS. See Circum-

fiexus.

PALATI LEVATOR. See Levator palati.
PALATI TENSOR. See Circumflexus.

PALATO-PHARYNGEUS. (Jeusculus palato pharyngeus; so called from its origin in the palate and insertion in the pharynx.) Thyreo-staphilinus of Douglas. Thyreo-pharyngo-staphilinus of Winslow, and palato-pharyngien of Dumas. A muscle situated at the side of the entry of the fauces. It arises by a broad beginning from the middle of the velum pendulum palati at the root of the uvula posteriorly, and from the tendinous expansion of the circumflexus palati. The fibres are collected within the posterior arch behind the tonsils, and run backwards to the top and lateral part of the pharynx, where the fibres are scattered and mixed with those of the style-pharyngeus. It is inserted into the edge of the upper and back part of the thyroid cartilage. Its use is, to draw the uvula and velum pendulum palati downwards and backwards, and at the same time to pull the thyroid cartilage and pharynx upwards, and shorten it; with the constrictor superior pharyngis and tongue, it assists in shutting the passage into the nostrils; and in swallowing, it thrusts the food from the fauces into the pharynx.

PALATO-SALFING.EUS. (From palatum, the palate, and σαλπηξ, a trumpet; so called from its origin in the palate, and its trumpet-like shape.) See Circumflexus.

PALATO-STAPHILINUS. See Azygos uvu-

læ.

PALATUM. (From palo, to hedge in, because it is staked in, as it were, by the teeth.) The palate, or roof of the mouth.

PALATUM MOLLE The soft palate. This lies behind the bony palate; and from the middle of it the uvula hangs down.

PALEA DE MECHA. A name given by some to the Juncus Odoratus.

PALIMPISSA. (From waln, repetition, and wirea, pitch.) Dioscorides says, that dlry pitch is thus named, because it is prepared of pitch twice boiled.

PALINDROMIA. (II ax 1, again, and Seo-

μος, a course.) Is used by Hippocrates for any recurritation of humours to the more noble parts: and sometimes for the return of a distemper.

Paliurus. (From σαλλω, to move, and sgo, urine; so called from its diuretic qualities.) A species of white thorn.

PALLIATIVA. (From pallie, to dissemble.) Medicines given only with an intent to relieve pains in a fatal disease.

PALM OIL. Oleum palm.e. This oil 13 produced chiefly from the fruit of the Cocos butyracea of Linnæus :- inernis, frondibus pennatis : foliolis simplicibus, by bruising and dissolving the kernels of the fruit in water, without the aid of heat, by which the oil is separated, and rises to the surface, and, on being washed two or three times, is rendered fit for use. When brought into this country, it is of the consistence of an ointment, and of an orange yellow colour, with little taste, and of a strong, though not disagreeable, smell. Its use is confined to external applications in pains, tumours, and sprains; but it appears to possess very little if any advantage over other bland oils.

PALMA. (From TALLAW, to move.)

1. The palm of the hand.

2. The name of a genus of plants in the Linnxan system, so called because the leaves are extended from the top, like the fingers upon the hand.

PALMA CHRISTI. See Ricinus.

PALMARIS BREVIS. (Palmaris, from palma, the hand.) Palmaris brevis vel caro quadrata of Douglas, and Palmare cutané of Dumas. A small, thin, cutaneous, flexor muscle of the hand, situated on the fore-arm, between the wrist and the little-finger. Fallopius tells us that it was discovered by Cananus. Winslow names it palmaris cataneus. It arises from a small part of the internal annular ligament, and inner edge of the aponeurosis palmaris, and is inserted by small bundles of fleshy fibres into the os pisiforme, and into the skin and fat that cover the abductor minimi digiti. This muscle seems to assist in contracting the palm of the hand

PALMARIS CUTANEUS. See Palmaris

brevis

PALMARIS LONGUS. Ulnaris gracilis of Winslow, and Epitrochlo carpi palmaire of Dumas. A flexor minscle of the arm, situated on the fore-arm, immediately under the integuments. It arises tendinous from the inner condyle of the os himeri, but soon becomes fleshy, and after continuing so about three inches, terminates in a long slender tendon, which, near the wrist, separates into two portions, one of which is inserted into the internal annual r ligament, and the other loses itself in a tendinous membrane, that is nearly of a triangular shape, and extends over the

palm of the hand, from the carpal ligament to the roots of the fingers, and is called aponeurosis palmaris. Some of the fibres of this expansion adhere strongly to the metacarpal bones, and separate the muscles and tendous of each finger. Several anatomical writers have considered this aponeurosis as a production of the tendon of this muscle, but seemingly without reason, because we now and then find the latter wholly inserted into the carpal ligament, in which case it is perfectly distinct from the aponeurosis in question; and, in some subjects, the palmaris longus is wanting, but the aponeurosis is always to be found. Rhodius, indeed, says that the latter is now and then deficient; but there is good reason to think that he was mistaken. This muscle bends the hand, and may assist in its pronation; it likewise serves to stretch the aponeurosis palmaris.

PALMOS. (From wanne, to beat.)

palpitation of the heart

PALMULA. (Dim. of palma, the hand; so called from its shape.) 1. A date.

2. The broad and flat end of a rib.

PALPEBRÆ. (A palpitando, from its frequent motion.) The eyelids, distinguished into upper and under: at each end they unite and form the canthus.

Pulpebræ superioris levator. See Levator

palpebræ superioris.

palpebræ superioris.

PALPITATIO. 1. A palpitation or

convulsive motion of a part.

2. Palpitation of the heart, which is either constant or frequently returning. A genus of disease in the class Neurosis, and order Spasmi, of Cullen.

Palsy. Sec Paralysis.

PALUDAPIUM. (From palus, a lake, and apium, smallage; so named because it grows in and about rivulets.) A species of smallage.

PALUS SANCTUS. A

PANPHILIUM. (From was, all, and wi-205, grateful; so called from its extensive usefulness.) A plaster described by Ga-

Pampiniformis. (From pampinus, a tendril, and forma, a likeness.) Resembling a tendril; applied to the spermatic chord

and the thoracic duct.

was, all, and automai, to cure.) An epithet given by the antients to those remedies which they conceived would cure every disease. Unfortunately for those of the present day there are no such remedies.

of potash.

L'ANACEA DUPLICATA. ash.

PANACEA VEGETABILIS. Saffron.

PANADA. (Dim. of pane, bread, Ital.) Panata. Panatella. Bread boiled in water to the consistence of pap. Dry biscuits soaked are the best for this purpose.

PANALETHES. (From may, all, and annons, true.) A name of a cephalic plaster,

from its universal efficacy.

Corrupted from parony-PANARITIA.

PANARIS. (Corrupted from paronychia.) See Paronychia

PANAVA. See Lignum pavana.

PANAX. (From mar, all, and axes, 2 cure.) The pharmacopocial name of Hercules's allieal or wound wort. Laserpitium chironium of Linnaus The seeds and roots of this plant are warm, and similar in flayour and quality to those of the parsnip. The roots and stalks have a much stronger smell, which resembles that of opoponax, and Boerhave relates, that on wounding the plant in the summer, he obtained a yellow juice, which being inspissated a little in the sun, agreed perfectly in both respects with that exotic gum resin.

PANAX QUINQUEFOLIUM. The systematic name of the plant which affords the

ginseng root. See Ginseng.

PANCHESTOS. (From may, all, xeesos, useful, so named from its general usefulness.) Panchreston. An epithet of a collyrium described by Galen. It is also of Palpebrum aperiens rectus. See Levator the same signification as Panacea, but little used.

PANCHYMAGOGA. (From way, all, xumos, succus, humour, and ayo, duco, to lead or draw.) Is ascribed to such medicines as are supposed to purge all humours equally alike: but this is a conceit now not minded.

PANCOENUS. (From Tas, all, and ROLVOS. common ) Epidemic; applied to popular diseases, which attack all descriptions of

persons.

PANCRATIUM. (From mas, all, and name of guaia- xeatew, to conquer; so called from its virtues in overcoming all obstructions.) See

PANCREAS. (From mas, all, and xgeas, flesh; so called from its fleshy consistence.) A glandular viscus of the abdomen, of a long figure, compared to a dog's tongue, situated in the epigastric region under the stomach. It is composed of innumerable small glands, the excretory ducts of which PANACEA. (From war, the neuter of unite and form one duct, called the pancreatic duct, which perforates the duodenum with the ductus communis choledochus, and conveys a fluid, in its nature similar to saliva, into the intestines. The pancreatic artery is a branch of the splee PANACEA DUC HOLSATIE. The sulphate nic. The veins evacuate theniselves into the splenic vein. Its nerves are from the Sulphate of pot- par vagum and great intercostal. The use of the pancreas is to secrete the pancreatic juice, which is to be mixed with the 4 G

chyle in the duodenum. The quantity of the fluid secreted is uncertain; but it must be very considerable, if we compare it with the weight of the saliva, the pancreas being three times larger, and seated in a warmer place. It is expelled by the force of the circulating blood, and of the incumbent viscera in the full abdomen; as the liver, stomach, spleen, mesenteric and splenic arteries, and the aorta. Its great utility appears from its constancy, being found in almost all animals; nor is it refuted by the few experiments in which a part of it was cut out from a robust animal, without occasioning death; because the whole pancreas cannot be removed without the duodenum: for even a part of the longs may be cut out without producing death, but they are not therefore useless. It seems principally to dilute the viscid cystic bile, to mitigate its acrimony, and to mix it with the food. Hence it is poured into a place remote from the cystic duct, as often as there is no gallbladder. Like the rest of the intestinal humours, it dilutes and resolves the mass of aliments, and performs every other office of the saliva.

Pancreatic duct. See Ductus pancreaticus.

Parcreatic juice. See Pancreas.

PANCRENE. (From mas, all, and nenun, a fountain ) A name of the pancreas from its great secretion.

PANDALITIUM. A whitlow.

PANDEMIC. (Pandemicus; from mar, all, and demos, the people ) A synonym of epidemic. See Epidemic.

PANDICULATIO. (From pandiculo, to gape and stretch.) Pandiculation, or that restless stretching and gaping which accompanies the cold fit of an ague.

PANICUM. (A paniculis, from its many particles; the spike consisting of innumerable thick seeds, disposed in many panicles.) The name of a genus of plants in the Linnxan system. Class, Triandria, Order, Digynia.

The systematic PANICUM ITALICUM. name of the plant which affords the Indian millet-seed See Millet-seed, Indian.

PANICUM MILIACEUM. The systematic let seed. See Millet-seed

PANIS CUCULIS. See Acetosella.

Panis porcinus. A species of cycla-

PANNICULUS. (From pannus, cloth.) 1. A piece of fine cloth.

2. The cellular and carnous membranes are so called from their resemblance to a piece of fine cloth.

PANNONICA. (From pannus, a rag; so called because its stalk is divided into many uneven points, like the end of a piece of rag.) Hawkweed.

PANNUS. (From meyo, to labour.) 1, A piece of cloth.

2. A tent for a wound.

3. A speck in the eve, resembling a bit

4. An irregular mark upon the skin.

PANOCHIE. Buboes in the groin.

PANOPHOBIA. (From may, all, and φοδος, fear.) That kind of melancholy which is attended with groundless fears.

Pansies. See Viola triocolor.

Pantagoga. (From mas, all, and ayo, to drive out.) Medicines which expel all morbid humours.

PANTOLMIUS. (From mas, all, and Toxμαω, to dare; so named from its general uses.) A medicine described by Ægine-

PANTOPHOBIA. The same as hydropho-

Panus. (From mera, to work.) 1. A weaver's roll.

2. A soft tumour shaped like a weaver's

PAPAVER. (Papaver, from pappa, pap; so called because nurses used to mix this plant in children's food to relieve the colic and make them sleep.) 1. The name of a genus of plants in the Linnæan system. Class, Polyandria. Order Mo-

nogynia. The poppy

2. The pharmacopeial name of the white poppy. Papaver album. Papaver somnife-rum of Linnxus:—calycibus capsulisque glabris, foliis amplexicaulibus incisis. It is from heads of this plant that the opium is obtained. See Opium They are also directed for medicinal use in the form of fomentation, and in the syrupus papaveris, a useful anodyne, which often succeeds in procuring sleep where opium fails; it is, however, more especially adapted to children. The seeds of this species of poppy contain a bland oil, and in many places are eaten as food; as a medicine, they have been usually given in the form of emulsion in catarrhs, stranguries, &c.

PAPAVER ERRATICUM. Red or corn poppy. Papaver rheas of Linnaus:-capsulis glabris globosis, caule piloso multifloro, foliis pennatifidis incisis. The heads of this species, like those of the somniferum, name of the plant which affords the mil- contain a milky juice of a narcotic quality; from which an extract is prepared, that has been successfully employed as a sedative. The flowers have somewhat of the smell of opium, and a mucilaginous taste, accompanied with a slight degree of bitterness. A syrup of these flowers is directed in the London Pharmacopaia, which has been thought useful as an anodyne and pectoral, and is prescribed in coughs and catarrhal affections. See Syrupus rhæados.

PAPAVER NIGRUM. The black poppy. The seeds and heads of the paparer somni-

ferum, are also called in some pharmacopœias semina and capitula papaveris nigra. See Papaver.

PAPAVER RUBAS. The systematic and pharmacoperal name of the red corn pop-

py. See Papaver erraticum

PAPAVER SONVIFERUM. The systematic name of the white poppy. See Papa-

ver erraticum.

PAPAW. The fruit of the Carica papapa of Linnæus, a native of both Indics, and Guinea coast of Africa. When the roundish fruit are nearly ripe, the inhabitants of India boil and eat them with their meat, as we do turnips. They have somewhat the flavour of a pompion. Previous to boiling, they soak them for some time in salt and water, to extract the corrosive juice, unless the meat they are to be boiled with should be very salt and old, and then this juice being in them will make them as tender as a chicken. But they mostly pickle the long fruit, and thus they make no bad succedancum for mango. The buds of the female flowers are gathered, and made into a sweetmeat; and the inhabitants are such good husbands of the produce of this tree, that they boil the shells of the ripe fruit into a repast, and the insides are caten with sugar in the manner of melons.

PAPILLA. 1. The nipple of the breast.

See Nipple.

2. The fine terminations of nerves, &c. as the nervous papillæ of the tongue, skin, &c.

PAPILLE MENULLARES. Small eminences on the medulla oblongata.

Papillanis Herba. Sec Lapsana.

Papres. The hair on the middle of the chin. See Capillus.

PAPULA. (Papula, dim. of pappa, a dug or nipple.) A very small and accuminated clevation of the cuticle, with an inflamed base, not containing a fluid, nor tending to suppuration. The duration of papula is uncertain, but they terminate for the most part in seurf.

PAN CUCULLANE. So Casserius calls the

Musculus Crico Arytænoideus.

PAR VAGUM. (Par, a pair.) The eighth pair of nerves. They arise from the corpora olivaria of the medulla oblongata, and proceed into the neck, thorax, and abdomen. In the neck the par vagum gives off two branches, the lingual and superior laryngeal; and, in the thorax, four branches, the recurrent laryngeal, the cardiac, the pulmonary, and the esophageal plexuses. At length the trunks of the nervi vagi, adjacent to the mediastinum, run into the stomach, and there form the stomachic plexus, which branches to the abdominal plexuses.

PARACENTESIS. (From @aganertem, to pierce through.) The operation of tup-

ping to evacuate the water in ascites, dropsy of the ovarium, uterus, &c.

PARACHASTICOS. (From maganhaga, to decline.) Paracme. The decleusion of any distemper; also, according to Galen, that part of life, where a person is said to grow old, and which he reckons from 35 to 49, when he is said to be old.

PARACOE. (From #aga, dim, and anew, to hear.) Difficult hearing; dulness of

hearing.

PARACOLLETICA. (From παξακολλομαι, to glue together.) Agglutinants; substances which unite parts preternaturally separated.

PARACOPE. (From παζακοπτω, to be delirious.) In Hippocrates it is a slight

delirium.

PARACRUSIS. (From magazese, to depreciate.) A slight disarrangement of the faculties, where the patient is inattentive

to what is said to him.

PARACUSIS. (From σαρα, wrong, and ακκω, to hear.) Depraved hearing. Deafnoss. A genus of disease in the Class Locales, and Order Dysasthesia of Cullen. There are two species, 1. Paracusis impersecta. Surditas. When existing sounds are not heard as usual. 2. Paracusis imaginaria, called also susurrus. Syringmus. Syringmos. Timitus aurium. When maginary sounds are heard, not from without, but excited within the ear.

Panacrnanche. From  $\pi \alpha g \alpha_s \kappa u \omega v_s$ , a dog, and  $\omega \gamma \chi \omega_s$ , to strangle.) A species of Quinsy: it being a distemper to which dogs

are subject.

Paranetes. (Heb.) A pungent seed resembling the cardamom, is named granum paradisi, from its virtues

Paradisi grana. See Grana paradisi.

Parageossa. (From  $\pi \alpha g \alpha$ , and  $\gamma \lambda \alpha \sigma \sigma \alpha$ , the tongue.) A prolapsus of the tongue, a swelled tongue.

Panagoge. (From παζαγα, to adduce.) Signifies that fitness of the bones to one another, as is discernible in their articulation; and bones which are thereby easier of reduction, when dislocated, are by Hippocrates called παζαγαγοτέζα.

PARALAMPSIS. (From πας αλαμπω, to shine a little.) Some writers use this word to express a cicatrix in the transparent part of the cornea of the eye.

PARALLAGMA. (From raganatra, to change.) Parallaris. The transmutation of a solid part from its proper place, as where one part of a broken bone lies over another.

PAHALLAKIS. See Parallagma.

PAHALLELA. (From παςαλληλος, parallel.) A sort of seurf or leprosy, affecting only the palms of the hands, and running down them in parallel lines; it happens sometimes in the venereal disease.

absurdly.) A delirium in which the pa-

tient talks wildly.

PARALOPHIA. (From Taga, near, and λοφια, the first vertebra of the back.) Thus some anatomical writers, as Keil, &c express the lower and lateral part of the neck near the vertebræ

PARALYSIS. (From παζαλυω, to loose or weaken.) Catalysis. Attonitus morbus. Stupor. Tremor. The palsy. A genus of disease in the Class Neuroses, and Order Comata, of Cullen, known by a loss or diminution of the power of voluntary motion, affecting certain parts of the body, often accompanied with drowsiness. some instances, the disease is confined to a particular part; but it more usually happens that one entire side of the body from the head downwards is affected. The species are: 1. Paralysis partialis, partial, or palsy of some particular muscle. 2. Paralysis hemiplegica, palsy of one side, longitudinally. 3 Paralysis paruplegica, palsy of one half of the body, taken transversely, as both legs and thighs. 4. Paralysis venenata, from the sedative effects of poisons. Paralysis is also symptomatic of several diseases, as worms, scrophula, syphilis, &c.

It may arise in consequence of an attack of apoplexy. It may likewise be occasioned by any thing that prevents the flow of the nervous power from the brain into ungos, the thigh.) The inward parts of the the organs of motion; hence tumours, over distention and effusion, often give rise to it. It may also be occasioned by morbid matter to the head, by the suppression of usual evacuations, and by the pressure made on the nerves by luxations, fractures, wounds, or other external injuries. The long continued application of sedatives will likewise produce palsy, as we find those, whose occupations subject them to the constant handling of white lead, and those who are much exposed to the poisonous fumes of metals, or minerals, are very apt to be attacked with it. Whatever tends to relax and enervate the system, may likewise prove an occasional

cause of this disease.

Palsy usually comes on with a sudden and immediate loss of the motion and sensibility of the parts; but in a few instances, it is preceded by a numbness, coldness, and paleness, and sometimes by slight convulsive twitches. When the head is much affected, the eye and mouth are drawn on one side, the memory and judgment are much impaired, and the speech is indistinct and incoherent. If the disease affects the extremities, and has been of long duration, it not only produces a loss of motion and sensibility, but likewise a considerable flaccidity and

(From παραλεγω, to talk wasting away in the muscles of the parts

When palsy attacks any vital part, such as the brain, heart, or lungs, it soon terminates fatally. When it arises as a consequence of apoplexy, it generally proves very difficult of cure. Paralytic affections of the lower extremies ensuing from any injury done to the spinal marrow, by blows and other accidents, usually prove incurable. Palsy, although a dangerous disease in every instance, particularly at an advanced period of life, is sometimes removed by the occurrence of a diarrhea or fever.

The morbid appearances to be observed on dissections in palsy, are pretty similar to those which are to be met with in apoplexy; hence collections of blood, and of serous fluids, are often found effused on the brain, but more frequently the latter, and in some instances the substance of this organ seems to have suffered an alteration. In palsy, as well as in apoplexy, the collection of extravasated fluid is generally on the opposite side of the brain to that which is affected.

PARALYSIS HERBA. (From παραλυω, to weaken; so called from its use in paralytic disorders.) The cowslip and primrose are sometimes so termed. See Primula veris, and Primula vulgaris.

PARAMERIA. (From maga, near, and thigh.

Paramesus. (From maga, near, and meros, the middle.) The ring finger, or that which is between the middle and the little fingers.

PARANCEA. (From maga, dim, and voew, to understand.) Alienation of mind; de-

ranapechyum. (From πaga, near, and παχυς, the cubit.) That part of the

PARAPHORA. (From παζαφέζω, to trans. fer.) A slight kind of delirium, or lightheadedness in a fever: some use this word for a delirium in general.

PARAPHRENESIS. A delirium; also pa-

raphrenitis.

PARAPHROSYNE. (From Tagadeovew, to be estranged in mind.) The same as Ma-

PARAPHONIA. (From wags, wrong, and own, sound.) Alteration of the voice. A genus of discase in the Class Locales, and Order Dysciuesia of Cullen, comprehending six species, viz. paraphonia puberum, paraphonia ranca, paraphonia resonans, paraphonia palatina, paraphonia clangens, and paraphonia comatosa

PARAPHORA. (From magagego, to trans-A slight alienation of the mind.

PARAPHRENITIS. (From waga, dim,

and penv, the mind.) Diaphragmititis. An to cleave.) A fragment or fissure in a broinflammation of the diaphragm. A genus ken bone. of disease in the Class Pyrexia and Order with difficulty of breathing, and pain in mais and plants are so termed that rethe region of the diaphragm.

PARAPHYMOSIS. (From σαgα, about, others, as worms, polypes, hydatids, &c. and διμοφ, to bridle.) The paraphymo- Parasphagis. (From σαgα, near, and and φιμοω, to bridle.) The paraphymo-Paraseriagis. (From παξα, near, and sis is a disorder wherein the prepuce, being σφαγη, the throat.) The part of the neek retracted toward the root of the penis, cannot be returned again over the glans, corona. It is easily known; the glans is uncovered, the skin tumefied on the corostricture, which, from the skin being unequally extended, becomes indented, and makes several rings round the part. This disease may proceed from two causes; as first from the imprudence of young people, and sometimes also of grown persons, who baving the end of their prepuce too strait, cannot uncover their glans without pain, and when they have done it, neglect returning it so soon as they ought; and thus the contracted part of the prepuce forms a constriction behind the glans. Soon after, the glass and penis swell, and the prepuce being consequently very much distended, is affected in the same manner: an inflammation seizes upon both, and swellingsquickly appear upon the stricture formed by the prepuce, so that the whole dily relieved. The second thing that may produce a paraphymosis, is a venereal virus. In adults, whose glans is uncovered, camphorata. there frequently arise venereal chancres in the prepuce after impure coition, which before they digest, are generally attended with inflammation, more or less considerable. This inflammation is alone sufficient to render the prepuce too strait for the size of the penis, in consequence of which a swelling or inosculation may ensue like that before mentioned; and this is what is termed a paraphymosis.

PARAPLEGIA. (From παgaπλησσω, to strike inharmoniously.) Palsy of one half of the body taken transversely. A spe-

cies of paralysis. See Paralysis.

PAHAPOPLENIA. (From Taga dim, and ατοπληξία, an apoplexy.) A slight apo-

PARARTHRENA. (From ruga, and aggest, a joint ) A slight luxation; a tumour

from protrusion, as an hernia. PARABURHEMATA. Plural of pararthrema,

and synonymous with ectopice.

PANANYTHMOS. (From Taga, and gubucc, number.) A pulse not suitable to the age of the person.

PARASCEPASTRA. (From maga, and GRETZ (a, to cover.) A cap or bandage to go round the whole head.

PARASITIC. (Parasiticalis; Phlegmasic of Cullen, known by delirium, Tagaritos, a parasite or hanger on.) Aniceive their nourishment in the bodies of

contiguous to the clavicles.

l'anastata. (From magishui, to stand but makes a sort of ligature behind the near.) It signifies any thing situated near another.

PARASTATE. (From magiorepi, to stand na, and above it forms a circular collar or near.) In Hippocrates it signifies the Epididymis. Herophilus and Galen called these the Varicosa Parastata, to distinguish them from the Glandulosa Parastata, now called Prostate Rufus Ephesius called the tubæ Fallopianæ by the name of Parastatæ Varicosæ.

PARASTREMMA. (From TagaTTEEpw, to distort, or pervert.) A perversion, or convulsive distortion of the mouth, or any part of the face.

PARASTNANCHE. A species of Quinsy.

See Paracynanche.

PARATHENAN. (From maga, near, and Devag, the sole of the foot.) A muscle situated near the sole of the foot.

Parathenar minor. See Flexor brevis

minimi digiti pedis.

PARDALIUM. (From magsoc, the panmay be liable to a gangrene, if not spee- ther.) An ointment smelling like the pan-

Paregoric Elixir. See Tinctura opii

PAREGORICS. (Medicamenta paregorica, παζηγοςικος ; from σαζαγοςεω, to mitigate, to assnage.) Medicines that allay pain are so termed.

PAREIA, Hagera. That part of the face which is between the eyes and

PAREIRA BRAVA. See Pariera brava. PARENCEPHALIS. (From waga, near,

εγκεφαλος, the brain.) See Cerebellum. PARENCHYMA. (From Φαζεγκυο, to strain through, because the ancients believed the blood was strained through it.) The spongy and cellular substance that connects parts together. It is now only, in anatomy, applied to the connecting medium of the substance of the lungs.

PARESIS (From maginial, to relax.)

An imperfect palsy.

PARIERA BRAVA. (Span.) Pareyra. Ambutna. Butna. Overo butna. The root of this plant, Cissumpelos pareira of Linnans. foliis pellatis cordatis emarginatis. Class, Dioecia. Order, Monodelphia. native of South America and the West Indies, has no remarkable smell, but to the taste it manifests a notable sweetness of the liquorice kind, together with a PARASCHIVE. (From Taga, and oxiga, considerable bitterness, and a slight roughness covered by the sweet matter. The facts adduced on the utility of the radix pariere bruve in the nephritic and calculous complaints, are principally mentioned by foreigners, and no remarkable instances of its efficacy are recorded by English

practitioners.

PARIETAL BONES. (Parietalis, from paries, a wall, because they defend the brain like walls.) Ossa verticis. Ossa syncipitis. Ossa verticalia vel bregmatis. Two arched and somewhat quadrangular bones, situated one on each side of the superior part of the cranium. Each of these bones forms an irregular square. They are thicker above than below; but are somewhat thinner, and at the same time more equal and smooth than the other bones of Paris. The herb true love. Paris quadrithe cranium serve in them, is a small one towards the this plant indicate its possessing narcotic upper and posterior part of each. It. has been named the parietal foramen, and serves for the transmission of a small vein to the longitudinal sinus. In many subjects this foramen is wanting. On the inner surface of these bones are the marks of the vessels of the dura mater, and of the convoluted surface of the brain. On the inside of their upper edge we may likewise observe a considerable furrow, which corresponds with the longitudinal sinus of the dura mater; and lower down, towards their posterior and inferior angle, is a smaller one for part of the lateral sinuses. These bones are joined to each other by the sagittal suture; to the os sphenoides, and ossa temporum, by the squamous suture; to the os occipitis by the lambdoidal suture; and to the os frontis by the coronal suture. Their connexion with this latter bone is well worthy our attention. We shall find that in the middle of the suture, where the os frontis from its size and flatness is the most in danger of being injured, it rests upon the arch formed by the parietal bones; whereas at the sides, the parietal bones are found resting upon the os frontis because this same arch is there in the greatest danger from pressure. In new born infants, the ossa parietalia are separated from the middle of the divided os frontis by a portion of the cranium, then unossified. When the finger is applied to this part, the motion of the brain, and the pulsation of the arteries of the dura mater, may be easily distinguished. In general the whole of this part is completely ossified before we are seven years of age.

PARIETARIA. (From paries a wall; because it grows upon old walls, and among rubbish.) 1. The name of a genus of plants in the Linnaan system. Class,

Polygamia. Order, Monoecia.

The pharmacopæial name of the wall pellitory.

Linnæus :- foliis lanceolato-ovatis, peduneulis dichotomis, calycibus diphyllis plant has no smell, and its taste is simply herbaceous. In the practice of the present day it is wholly laid aside, although it was formerly in high estimation as a diuretic.

PARIETARIA OFFICINALIS. The systematic name of the wall pellitory. See Parietaria.

PARIS. (So called in reference to the youth of that name, who adjudged the golden apple to Venus, this herb bearing but one seed.) 1. The name of a genus of plants in the Linnaan system.

tandria. Order, Tetragyvia.

2. The pharmacopæial name of the herb The only foramen we ob- folia of Linnaus. The colour and smell of powers. The leaves and berries are said to be efficacious in the cure of hoopingcough, and to act like opium. Great caution is requisite in their exhibition, as convulsions and death are caused by an overdose. The root possesses emetic qualities.

Paris Quadrifolia. The systematic name of the herb Paris. See Paris.

PARISTHMIA. (From maga, and 108 mior: the part of the throat near which the tonsils are.) A part of the throat near the tonsils, or disorders of the tonsils.

PARISTHMIOTOMUS. (From wagiobuia, the tonsils, and reuve, to cut.) An instrument with which the tonsils were formerly scarified.

PARODONTIS. (From @202, near, and odss, a tooth.) A painful tubercle upon the

PARONYCHIA. (From waga, about and ovek, the nail.) Panaris. Panaritium. A whitlow, or whitloe. Any collection of pus formed in the fingers is termed by authors panaris, or whitloe, and is an abscess of the same nature with those arising in other parts of the body. These abscesses are situated more or less deep, which has induced the writers upon the subject to divide them into several species: accordingly they have ranged them under four heads, agreeable to the places where they are formed. The first kind of panaris is formed under the cuticle, on one side of the nail, and sometimes all round it. second is seated in the fat lying under the skin, between that and the sheath which involves the flexor tendons. The third is described by authors to be formed within the sheath; and they still add a fourth species, arising between the periosteum and the bone.

PAROPIE. (From waga, near, and wy, the eye.) The external angles of the

eyes.

PAROPTESIS. (From wagz, and onlaw, to Parietaria officinalis of roast.) A provocation of sweat, by mak-

ing a patient approach the fire, or by placing him in a bagnio.

PARORASIS. (From waga, dim, and cezw, to see.) An imbecility of sight.

PARORCHIDIUM. (From waga, and εεχις, a testicle.) A tumour in the groin, occasioned by the testicle, which is pass-

ing into the scrotum.

PAROTID GLAND. (Glandula parotidea; from raga, about, and se, the car.) Parotis A large conglomerate and salival gland, situated under the ear, between the mamillary process of the temple bone and the angle of the lower jaw. The excretory duct of this gland opens in the mouth, and is called, from its discoverer, the Stenonian duct

PAROTID.EA (From waparis, the parotid gland.) The trivial name of a species of quinsey, in which the parotid gland, neck and throat, are considerably affect-

cd. See Cynanche.

PAROTIS. (From waga, near, and es, the ear.) See Parotid gland.

PAROXYSM. (Paroxysmus; from σαςοξυνω, to aggravate.) A periodical exacerbation or fit of a disease.

Parsley, black mountain. See Oreoselimune.

Parsley, common. See Petroselinum.

Parsley, Macedonian. See Petroselinum Macedonicum. Parsnip. See Pastinaca.

Parsnip, water. See Sinm.

PARTHENIASTRUM. (Dim. of parthenium, tansy.) A species of tansy, or bastard feverfew.

PARTMENIS. The same as parthenium.

PARTHENIUM. (From wagbevog, a virgin; so called because of its uses in diseases of young women.) See Matrica-

PARTHENIUM MAS. See Tanacetum.

PARULIS, (From waga, near, and sxor, the gum.) An inflammation, boil, or abscess in the gums.

PARAGEON. (From waga, and vyeos, hum.d.) A liquid or moist preparation for allaying a topical inflammation.

PASIFILLUS. (From was, all, and place, grateful; from its general usefulness.) A name given to a vitriolic plaster.

Pasma. (From marra, to sprinkle

over.) See Catupasma Passa. (From pando, to spread.) In

Paracelsus it is a whitloe.

PASSA MINOR. See Uva passa minor. Passavanticus. (From &ac, all, and avaira, to dry up.) An epithet given by Schroder to a powder which dries up and evacuates morbid humours.

PASSIFLORA. of plants in the Linnaan system. Class, two slightly concave surfaces, of which the Gynandria. Order, Pentandria.

l'ASSITLORA LAURIFOLIA.

passion-flower. A native of Surinam. The fruit have a delicius smell and flavour, and are excellent for quenching thirst, abating heat of the stomach, increasing the appetite, recruiting the spirits, and allaying the heat in burning fevers.

Passiflora maliformis. Apple-shaped granadilla. The fruit of this species of passion flower is esteemed a delicacy in the West Indies, where it is served up at table in desserts: they are not unwhole-

Passion, cæliac. See Diarrhæa. Passion, hysteric. See Hysteria. Passion, ihac. See Iliac passion. PASSULE MAJORES. See Uva passa major.

Passulatum. (From passo, a fig, or raisin.) Is a term given by Dispensatory writers to some medicines, where raisins. are the chief ingredient, as the electarium passulatum, &c.

(From passa, a grape, or Passum.

raisin.) Raisin-wine.

PASTA REGIA. (From @2000, to sprinkle.) A lozenge, or small cake, sprinkled over with some dry powdered substance.

Pastillum. (Dim. of pasta, a lozenge.) Pastillus. A little lump of paste, or ball, made to take like a lozenge, a troch, or pastil.

PASTINACA. (A pasta; from its usefulness as a food.) 1. The name of a genus of plants in the Linnzan system. Class, Pentandria. Order, Digmia. Pars-

2. The pharmacopæial name of the parsnip. The cultivated or garden parsnip is the Pastinaca sativa of Linnæus:foliolis simpliciter pinnatis. Eluphoboscum. Its roots are sweet and nutritious, and in high esteem as an article of food. They possess an aromatic flavour, more especially those of the wild plant, and are exhibited in calculous complaints for their dirretic and sheathing qualities.

PASTINACA OPOPANAX. The systematic name of the plant which yields opopo-

nax. See Opoponax.

The systematic Pastinaca sativa.

name of the parsnip. See Pastinaca.
PATELLA. (Dim. of patina, a dish; so named from its shape.) Rotula. The knee-pan. A small flat bone, which, in some measure, resembles the common figure of the heart, with its point downwards, and is placed at the fore part of the joint of the knee. It is thicker in its middle part than at its edge. Anteriorly it is a little convex, and rough for the insertion of muscles and ligaments; posteriorly, it is smooth, covered with cartilage, and The name of a genus divided by a middle longitudinal ridge, into external one is the largest and deepest. Bay leaved They are both exactly adapted to the pul-

lev of the os femoris. The edges of this posterior surface are rough and prominent, where the capsular ligament is attached, rest.) It is a warm opiate, such as the and below is a roughness at the point of London College have called Confectio Opii, the bone, where the upper extremity of in their Dispensatory. It is the Paulina a strong tendinous ligament is fixed, which of Aristarchus, which is the same with the joins this bone to the tuberosity at the upper end of the tibia. This ligament is of considerable thickness, about an inch in breadth, and upwards of two inches in length. The rotula is composed internally of a cellular substance, covered by a thin bony plate; but its cells are so extremely minute, that the strength of the bone is, upon the whole, very considerable. In new-born children, it is entirely cartilaginous. The use of this bone seems to be, to defend the articulation of the joint of the knee from external injury. It likewise tends to increase the power of the muscles which act in the extension of the leg, by removing their direction farther from the centre of motion, in the manner of a pul- rieties, affording an wholesome nourishley. When we consider the manner in ment. which it is connected with the tibia, we find that it may very properly be considered as an appendix to the latter, which it follows in all its motions, so as to be to the tibia what the electanon is to the ulna; that of commamon, which it greatly resemwith this difference, however, that the rotula is moveable, whereas the olecranon is a fixed process. Without this mobility, for allaying obstinate vomitings. the rotatory motion of the leg would have been prevented.

PATHETICI. (Patheticus; from @abos, an affection; because they direct the eyes to express the passions of the mind.) Trochleutores. The fourth pair of nerves. They arise from the crura of the cerebellum laterally, and are distributed in the scurvy. musculus obliquus superior seu troch-

PATHOGNOMONIC (Pathognomonicus: from malos, a disease, and yirworw, to know.) A term given to those symptoms which are peculiar to a disease. They are also termed proper or characteristic symptoms.

PATHOLOGY. (Pathologia; from waθos, a disease, and λογος, a discourse.) The doctrine of diseases. It comprehends nosology, atiology, symptomatology, semio-

tics, and therapia.

PATIENTIA. (From patior, to bear, or suffer.) The name of the herb monk's rhubarh, from its gentle purging qualities. See Rhabarbarum

See Rhabarbarum Patience, garden. monachovum

(From pateo, to be PATOR NARIUM. opened.) The sinus, cavity, or chasmof

PATRUM CORTEX. (So called from the Jesuits, called fathers in the church of muscular fibres of the right auricle of the Rome, who first spread its use in Europe.) heart. See Cinchona.

PATURSA. The venereal disease.

PAULINA, CONFECTIO. (From @200, to Confectio Archigenis.

Paul's betony. See Veronica. PAVANA. See Liguum pavanæ.

PAVOR. (From paveo, to fear; so called from the dread there is of approaching or touching a person affected with it.) The

PEA. A species of pulse of great variety, and much in use as a nourishing article of diet.

Peach. See Persica. Pengle. See Primula veris. Pearl. See Margurita. Pearl-ashes. See Potash. Pearl-barley. See Hordeum.

PEAR. Of pears there are a many va-

Pecuepion. Huxediev. The perinaum. PECHURIM CORTEX. An highly aromatic bark, the produce of a species of Laurus It is extremely fragrant, like unto bles in its properties. In Lisbon it is much esteemed in the cure of dysenteries, and

PECHURIS. See Pechurim.

PECHYAGRA. (From wnxus, the cubit, and ayea, a seizure.) The gout in the el-

Pecnys. Hazus. The cubit, or elbow. PECHYTYRBE. An epithet for the.

Perquet's duct. See Thoracic duct. PECTEN. The pubes, or share-bone.

PECTINALIS. (Pectinalis, sc. musculus; so named from it arising at the pecten, or pubis.) Pectineus of authors, and Pubio femoral of Dumas. This is a small flat muscle, situated obliquely between the pubis and the little trochanter, at the upper and anterior part of the thigh. It arises broad and fleshy from all the anterior edge of the os pectinis, or pubis, as it is more commonly called, as far as its spine, and, descending obliquely backwards and outwards, is inserted by a short and broad tendon, into the upper and anterior part of the linea aspera of the os femoris, a little below the lesser trochan-This muscle serves to bend the thigh, by drawing it upwards and inwards, and likewise assists in rolling it ontwards.

PECTINATI MUSCULI (Pectinatus; from preten, a comb : so named from their supposed resemblance.) The fasciculated

Pectinæas. See Pectinalis.

Pectoralis. See Pectoralis major.

PECTORALIS MAJOR. pectoralis; from pectus the breast.) Pec- denied this use, and Albinus has omitted toralis of authors, and sterno-costo-clavio- it, probably because it does not take place humeral of Dumas. This is a broad, thick, in a natural state. fleshy, and radiated muscle, situated immediately under the integuments, and co- tieus of Albinus. Douglas and Cowper call vering almost the whole anterior part of this muscle Serratus minor anticus, and the breast. Winslow calls it pectoralis major, to distinguish it from the serratus anti- minor, and Dumas calls it Costo-coracoicus, which he has named pectoralis minor. It arises from the cartilaginous extremities muscle, situated at the anterior and lateral of the fifth and sixth ribs, from the last of part of the thorax, immediately under the which its tendinous fibres descend over the upper part of the obliquus externus and edges of the third, fourth, and fifth ribs, rectus abdominis, helping to form a part near where they join with their cartilages of the sheath in which the latter is inclu- by an equal number of tendinous and ded. It likewise springs from almost the fleshy digitations, which have been comwhole length of the sternum by short ten-dinous fibres, which evidently decussate and some other muscles, from their having those on the other side; and tendinous and a similar origin, or insertion, have gotten gins the fibres run in a folding manner to- cends, and is inserted by a flat tendon into the outer side of the groove which lodges downwards; and when that is fixed, it may the tendon of the long head of the biceps: likewise serve to elevate the ribs. some of its fibres likewise extend into that groove; and, from the lower part of this lia; from pectus, the breast.) Medicines tendon, which is spread near two inches that relieve disorders of the ehest. along the os humeri, we find it sending off other fibres, which help to form the fascia that covers the muscles of the arm. It often happens that that part of the pectoralis which arises from the clavicle, is separated from the inferior portion, so as to appear gizage. That disease of the body in which like a distinct muscle. This has induced lice are continually bred on the skin. Winslow to divide it into parts, one of the thoracic portion. Sometimes these two portions are inserted by separate tendons, which cross one another at the upper and inner part of the os humeri, the tendon of the thoracic portion being inserted at the outer edge of the bicipital groove, immediately behind the other. This muscle, Pediasmus. (From medion, a field.) An and the latissimus dorsi, form the cavity of epithet of a species of wild myrrh. the axilla, or arm-pit. PELADA. A species of baldness, a shedding of the hair from a venereal cause.

PELAGRA. The disease called the pelagra does not appear to have been noticed by any of our nosologists. Indeed few accounts of it have hitherto been published, although the peculiar symptoms with which it is attended, and the fatal consequences which generally ensue from it, render it equally curious and impor-In certain districts, as Milan and Padua, in Italy, where it is peculiarly prevalent, it is computed to attack five inhabitants out of every hundred. The following account of this singular disease is extracted from Dr. Jansen's treatise on the subject, who had seen the disease at Milan:

About the month of March or April, when the season invites the farmers to cultivate their fields, it often happens that a shining red spot suddenly arises on the back of the hand, resembling the common erysipelas, but without much itching or pain, or indeed any other particular inconvenience. Both men and women, girls and boys, are equally subject to it. Sometimes this spot affects both hands, without sometimes on the neck, and now and then, though very rarely, on the face. It is sometimes also seen on the breasts of women, where they are not covered by the clothes, but such parts of the body as are not exposed to the air, are very seldom little, producing numerous small tubercles of different colours; the skin becomes dry and cracks, and the epidermis sometimes the health is not the least impaired, the lancholy increases, and at length ends in patient performs all his rural labours as real mania. before, enjoys a good appetite, eats heartireturn at their accustomed periods, and in person accustomed to see the disease

the proper quantity. But what is most surprising is, that in the month of September, when the heat of the summer is over, in some cases sooner, in others later, the disorder generally altogether disappears, and the skin resumes it natural healthy appearance. This change has been known to take place as early as the latter end of May or June, when it has only been in its earliest stage. The patients, however, are not now to be considered as well; the disease hides itself, but is not eradicated: for, no sooner does the following spring return, but it quickly re-appears, and generally is accompanied with severer symptoms. The spot grows larger, the skin becomes more unequal and hard, with deeper cracks. The patient now begins to feel uneasiness in the head, becomes fearful, dull, less capable of labour, and much wearied with his usual exertions. He is exceedingly affected with the changes of the atmosphere, and impatient both of cold and heat. Nevertheless he generally gets through his ordinary labour, with less vigour and cheerfulness indeed than formerly, but still without being obliged to take to his bed : and, as he has no fever, his appetite continues good, and the chylopoietic viscera perform their proper functions. When the pelagra has even arrived at this stage, the returning winter, nevertheless, commonly restores the patient to apparent health; but the more severe the symptoms have been, and the deeper root the disease has taken, the more certainly does the return of spring produce it with additional appearing on any other part of the body. violence. Sometimes the disease in the Not uncommonly it arises also on the shins. skin disappears, but the other symptoms remain notwithstanding. The powers both of the mind and body now become daily more enfeebled; peevishness, watchings, vertigo, and, at length, complete melancholy, supervene. Nor is there a more distressing kind of melancholy any where affected; nor has it ever been observed to to be seen, than takes place in this disattack the palm of the hand, or the sole of ease. "On entering the hospital at Legthe foot. This red spot elevates the skin a nano," says Dr. Jansen, "I was astonished at the mournful spectacle I beheld, especially in the women's ward. There they all sat, indolent, languid, with downcast assumes a fibrous appearance. At length looks, their eyes expressing distress, weepit falls off in white furfuraceous scales; but ing without cause, and scarcely returning the shining redness underneath still conti- an answer when spoken to; so that a pernues, and, in some instances, remains son would suppose himself to be among through the following winter. Many complained of a burn- occasions some of the inhabitants to paying pain at night in the soles of the feet, little attention to it; although, in other which often deprived them of sleep. Some cases, it reaches its greatest height after with double vision; others with fatuity; the second or third attack. It appears others with visceral obstructions; others that this disease is not infectious, and with additional symptoms. Nevertheless, that the causes producing it are yet unasfever still keeps off, the appetite is unimpaired, and the secretions are regularly carried on. But the disease goes on increasing, the nerves are more debilitated, the legs and thighs loose the power of motion, stupor or delirium come on, and the melancholy terminates in confirmed mania. In the hospital at Legnano, I saw both men and women in this maniacal state. Some lay quiet; others were raving, and obliged to be tied down to the bed, to prevent them from doing mischief to themselves and others. In almost all these, the pulse was small, slow, and without any character of fever. One woman appeared to have a slight degree of furor uterinus; for, at the sight of men, she became merry, smiled, offered kisses, and by her gestures desired them to come towards her. Some were occupied in constant prayers; some pleased themselves with laughter, and others with other things. But it was remarkable, that all who were in this stage of the disease, had a strong propensity to drown themselves. They now begin to grow emaciated, and the delirium is often followed by a species of tabes. A colliquative diarrhoa comes on, which no remedy can stop, as also has been observed in nostalgia. Sometimes, in the pelagra, the diarrhoa comes on before the delirium, and the delirium and stupor mutually interchange with each other. The appetite often suddenly failed, so that the sick will sometimes go for near a week without tasting food. Not uncommonly it returns as suddenly, so that they eagerly devoured whatever was offered them, and this even at times when they are horridly convulsed. The convulsions with which they are attacked, are most shocking to see, and are of almost every kind, catalepsy excepted, which has been described by writers. I saw one girl in bed, who was violently distorted by opisthotonos every time she attempted to rise. Some are seized with emprosthotonos; and others with other species of tetanus. At length, syncope and death close the tragedy, often without any symptom of fever occurring through the whole course of the disease. The first stage of the pelagra, in which the local affection only takes place, Dr. Jansen observes, continues in some instances for a great length of time; persons being occasionally met with in whom it has lasted six or eight, or even fifteen years, disappearing regularly every win- and inferior part of the pelvis. One of

certained. It has been supposed, by some, to arise from the heat of the sun's rays; and hence it is now and then called mal de sole; but this does not produce any similar disease in other parts of the world, where it is in an equal or even much greater degree than at Milan; no disease, in any respect resembling it, having hitherto been noticed in such regions, except the lepra asturiensis described by Thicry, and after him by Sauvages. In this, a tremor of the head and trunk of the body takes place, which does not happen in the pelagra. This, however, is the principal difference in the two diseases.

PELARIUM (From wnlos, mud; so called from its muddy consistence.) A collyrium. Pelato salpingaus. See Circumflexus.

Pelecanus. (From wederaw, to perforate; so named from its curvature at the end resembling the beak of the Pelican.) 1. The Pelican.

2. An instrument to draw teeth.

Pelecinum. (From @exensuc, a hatchet; so called because its seeds are shaped like a two-edged hatchet.) The hatchet vetch.

Peliona. (From wexos, black.) An ecchymosis when liver-coloured.

Pelitory, bastard. See Ptarmica. Pellitory of Spain. See Pyrethrum. Pellitory, wall. Sec Parietaria

PELMA. (From @EAW, to move forwards.) The sole of the foot, or a sock adapted to the sole of the foot.

PELTALIS CARTILAGO. (From pelta, a buckler; so called from its shape.) The scutiform cartilage of the larynx.

PELVIC LIGAMENTS. The articulation of the os sacrum with the last lumbar vertebra, and with the ossa innominata, is strengthened by means of a strong transverse ligament, which passes from the extremity and lower edge of the last lumbar vertebra, to the posterior and internal surface of the spine of the ilium. O her ligaments are extended posteriorly from the os sacrum to the ossa ilia on each side, and, from the direction of their fibres, may be called the lateral ligaments. Besides these, there are many shorter ligamentous fibres, which are seen stretched from the whole circumference of the articulating surfaces of these two bones. But the most remarkable ligaments of the pelvis are the two sacro ischiatic ligaments. which are placed towards the posterior

these may be called the greater, and the ted the outlet. It is composed by the other the lesser sacro-ischiatic ligament, arch of the pubis and by the sciatic liga-The first of these is attached to the pos- ments; it is wide and dilatable, to perterior edge of the os sacrum, to the tubemit the delivery of the child, but which rosity of the ilium, and to the first of the being sometimes too wide, permits the three divisions of the os coccygis. Its child's head to press so suddenly, and other extremity is inserted into the inner with such violence upon the soft parts, surface of the tuberosity of the ischium. that the perineum is torn. At its upper part it is of considerable breadth, after which it becomes narrower, been sought for in the skull, as in the conbut expands again before its insertion into tinuation of the sagital suture; but the the ischium, and extending along the tu- truest marks are those which relate to that berosity of that bone to the lower branch of the os pubis, where it terminates in a point, forms a kind of falx, one end of which is loose, while the other is fixed to the bone. The lesser sacro-ischiatic ligament is somewhat thicker than the former, and is placed obliquely before it. It bones, and with every peculiarity which extends from the transverse processes of may conduce to the easy passage of the the os sacrum, and the tuberosity of the spine of the ilium, on each side, to the spine of the ischium. These two ligaments not only serve to strengthen the articulation of the ossa innominata with the os sacrum, but to support the weight of the viscera contained in the pelvis, the back and lower part of which is closed by these ligaments. The posterior and external of the small intestines, and to give supsurface of the greater ligament likewise serves for the attachment of some portions of the gluteus maximus and gemini muscles. The symphysis pubis is strengthened internally by a transverse ligament, some of the fibres of which are extended to the obturator ligament.

PELVIS. (From weave, a basin, because it is shaped like a basin used in former times.) The cavity below the belly. The pelvis consists, in the child, of many pieces, but, in the adult, it is formed of four large bones, of the os sacrum behind, the ossa innominata on either side, and the os cocygis below. See Os sacrum, Ossa innominata, and Os cocygis. It is wide and expanded at its upper part, and contracted at its inferior aperture. The upper part of the pelvis, properly so called, is bounded by an oval ring, which parts the cavity of the pelvis from the cavity of the abdo-

The marks of the female skeleton have great function by which chiefly the sexes are distinguished; for while the male pelvis is large and strong, with a small cavity, narrow openings, and bones of greater strength, the female pelvis is very shallow and wide, with a large cavity and slender child.

The office of the pelvis is to give a steady bearing to the trunk, and to connect it with the lower extremities, by a sure and firm joining, to form the centre of all the great motions of the body, to contain the internal organs of generation, the urinary bladder, the rectum, and occasionally part port to the gravid uterus.

PELVIS AURIUM. The cochlea in the

PELVIS CEREBRI. The infundibulum in the brain.

Pemphigodes. (From σεμφίξ, a blast of wind.) A fever distinguished by flatulences and inflations, in which a sort of aërial vapour was said to pass through the skin.

PEMPHIGUS. (From σεμφιέ, a bubble, or vesicle.) Febris bullosa. Exanthemuta serosa, Morta. Pemphigus helveticus. Pemphigus major. Pemphigus minor. The vesicular fever. A fever attended by successive eruptions of vesicles about the size of almonds, which are filled with a yellowish scrum, and in three or four days subside. The fever may be either synocha or typhus. It is a genus of disease in the Class Pyrexia and Order Exanthemata of men This circle is denominated the brim Cullen. about, and xovdgos, a cartilage.) The membrane that covers a cartilage.

χειω, to anoint.) Any medicines with which the eyelids are anointed, in an opthalmia.

Periclasis. (From wegi, about, and κλαω, to break.) It is a term used by Galen for such a fracture of the bone as quite divides it, and forces it through the flesh into sight. Or a fracture with a great wound, wherein the bone is laid bare.

l'enicly venum. (From weginduza, to roll round; so called because it twists itself round whatever is near it.) The ho-

ney-suckle, or woodbine.

PERICRANIUM. (From weet, about, and xe zrior, the cranium.) The membrane that is closely connected to the bones of the head.

Peridesmica. (From wigi, about, and Sequec. a ligature.) Applied to an ischuria, or suppression of urine, from stricture in the urethra.

PERIDRONOS. (From wegs, about, and Seques, a course.) The extreme circumference of the hairs of the head.

Peniengia. Hegiegyta Is any needless caution or trouble in an operation, as rigingy oc. is one who despatches it with

PERIBLEPSIS. (From σεριβλέπω, to terms are met with in Hippocrates, and

Periestecos. (From weguothui, to sur-Penibole. (From περιθαλλώ, to sur-round, or to guard.) An epithet for dis-

PERIGRAPHE. (From wegizeaque, to cir-PERIBROSIS. An ulceration, or ero- cumscribe.) An inaccurate description, nifies certain white lines and impressions, observable in the museulus rectus of the abdomen.

Penin. (From wnga, a bag.) A testiele, Some explain it the Perinaum; others say it is the Anus.

PERINÆOCELE. (From wegivator, the perinæum, and κηλη, a rupture.) A rup-

ture in the perinaum.

PERINÆUM. (From wegiven, to flow round, because that part is generally moist.) The space between the anus and organs of generation.

Perinaus transversus. See Transversus

PERINYCTIDES. (From megi, and wot, the night.) Little swellings like nipples ; or, as others relate, pustules, or pimples,

which break out in the night.

PERIOSTEUM. (From wegi, about, and oseov, a bone.) The membrane which invests the external surface of all the bones, except the crowns of the teeth. It is of a fibrous texture, and well supplied with arteries, veins, nerves, and absorbents. It Pericurisis. (From εεξι, about, and is called pericranism, on the eranium; pericrbita, to anoint.) A liniment.

Pericurista. (From εεξι, around, and it covers cartilage; and peridesmium, when it covers ligament. Its use appears to be to distribute the vessels on the external surfaces of bones.

PERIPHIMOSIS. See Phimosis.

Peripleumonia. See Pneumonia.

PERIPNEUMONIA. (From wegt, and www. the lung.) Peripneumony, or inflammation of the lungs. See Pneumonia.

PERIPNEUMONIA NOTHA. Bastard or spurious peripneumony. Practitioners, it would appear, do not all affix this name to the same disease; some affirming it to be a rheumatic affection of the respiratory muscles, while others consider it as a mild peripneumony. It is characterised by difficulty of breathing, great oppression at the chest, with obscure pains, coughs, and oceasionally an expectoration. Spurious peripneumony is sometimes so slight as to resemble only a violent catarrh; and, after the employment of a few proper remedies, goes of by a free and copious expectoration; but sometimes the symptoms run high, and an effusion of serum into the brochiæ takes place, which destroys the patient.

PERIPYEMA. (From wegt, about, and wucr, pus.) Is a collection of matter about unnecessary circumstances: both the any part, as round a tooth in the gums: vuui, to break.) A breaking off, or a sepa- pletes the septum, in conjunction with the ration round about, either of corrupted pleura, with which it is continuous thro' bones or of dead flesh.

about.) Is a reflux of humours from the neys; anteriorly, behind the abdominal habit of the body into any of the larger muscles; it dips into the pelvis; from the emunctories for its excretion, as in an hy- bones of the pubis, passes over the bladdropsical case, of water upon the bowels der, and descends behind; and being again or kidneys, where it passes away by urine, carried backwards, at the entrance of the

them but once in their life. The discuse are often repeated without any evident ears. cause; but in many cases, the contagion may depend upon various exciting causes, such as violent exercise, a full meal, the having taken food of difficult digestion, and irritation of the lungs by dust, smoke, or disagrecable odours. Emotions of the mind may likewise prove an exciting cansc.

Its proximate or immediate cause seems to be a viscid matter or phlegm lodged about the bronchiæ, trachea, and fauces, which sticks so close as to be expectorated with the greatest difficulty. Some have supposed it to be a morbid irritability of the stomach, with increased actions of its mucous glands; but the affection of the stomach which takes place in the disease, is clearly only of a secondary nature, so that this opinion must be erro-

The hooping-cough usually comes on with a difficulty of breathing, some degree of thirst, a quick pulse, and other slight febrile symptoms, which are succontinue perhaps for a fortnight or more, at the end of which time the disease puts on its peculiar and characteristic form, and is now evident, as the cough becomes convulsive, and is attended with a peculiar sound, which has been called a hoop.

When the sonorous inspiration has happened, the coughing is again renewed, and found in a hard and enlarged state. continues in the same manner as before, ill either a quantity of mucus is thrown vianum.

months, or even a year.

Although the hooping-cough often proves tedious, and is liable to return with violence on any fresh exposure to cold, when not entirely removed, it nevertheless is seldom fatal, except to very young children, who are always likely to suffer more from it than those of a more advanced age. The danger seems indeed always to be in proportion to the youth of the person, and the degree of fever, and difficulty of breathing, which accompany the disease, as likewise the state of debility which prevails.

It has been known in some instances to terminate in apoplexy and suffocation. If the fits are put an end to by vomiting, it may be regarded as a favourable symptom, as may likewise the taking place of a moderate and free expectoration, or the ensuing of a slight hamorrhage from the

nose or ears.

Dissections of those who die of the coded by a hoarseness, cough, and diffi-culty of expectoration. These symptoms hooping-cough usually shew the consequence of the organs of respiration being affected, and particularly those parts which are the seat of catarrh. When the disease has been long protracted, it is apt to degenerate into pulmonary consumption, asthma, or visceral obstructions, in which last case the glands of the mysentery are

PEUCEDANUM. (From TEURN, the pine-tree; so called from its leaves resembling those of the pine-tree.) 1. The name of a genus of plants in the Linnzan Petreeleum. (From 76762, a rock, and system. Class, Pentandria. Order, Diskator, oil.) An oil or liquid bitumen which gynia. 2 The pharmacopæial name of the hog's fennel and sulphur-wort. Mara-PETROLEUM. (From petra, a rock, thrum sylvestre. Marathrophyllum. Pinasand oleum, oil.) The name of petroleum tellum. Herialeum porcinum. The plant is given to a liquid bituminous substance which bears these names in the pharmawhich flows between rocks, or in different copaias is the Peucedanum officinale of places at the surface of the earth. The Linnaus:-foliis quinque partitis, filiformimore fluid species are distinguished by bus linearibus. The root is the officinal the name of naphtha, and the thicker by part; it has a strong fetid smell, somethose of pissaphaltum and pissellum. See what resembling that of sulphureous solutions, and an acrid, unctuous, bitterish Barbadoes taste. Wounded, when fresh in the spring ployed externally in paralytic diseases.

Petroleum nunum. Oleum gabianum. juice, which soon dries into a solid gummy Red petroleum. A species of rock-oil of resin, which retains the taste and strong

PEUCEDANUM OFFICINALE. The systematic name of the hog's fennel. See Peu-

Percenanum silaus. The systematic asthmas, and other affections of the chest. name of the meadow saxafrage. See Sux-

PEYRHI GLANBULE. Peyer's glands. Brunnier's glands. Small glands situated

PEZIZA AURICULA. See Auricula juda. PHENOMENA. Phenomenon. (From oziva,

PHAGEDÆNA. (From caya, to eat.)

PHACEDENICS. (Phagedenica, sc. me-

PHALANGOSIS. (From \$\phi \alpha \alpha \gamma \gamma \beta \sigma \text{ a row of soldiers.) 1. An affection of the eye-lids, where there are two or more rows of hairs upon them.

2. A morbid inversion of the eyelids.

PHALANX. (From φαλανξ, a battalion.) The small bones of the fingers and toes, which are distinguished into the

first, second, and third phalanx.

PHALARIS CANARIENSIS. (From \$\phi aloss, white, shining; so named from its white, shining seed, and canariensis, from its being the principal food of the canary-birds.) Canary-grass. The seed of this plant is well known to be the common food of canary-birds. In the Canary islands, the inhabitants grind it into meal, and make a coarse sort of bread with it.

PHALLUS ESCULENTUS. The systematic name of the morel fungus. See Morel.

PHANTASMA. (From φανταζω, to make appear.) Imagination. Depraved vision.

PHARICUM. (From Pharos, the island from whence it was brought.) A violent

kind of poison.

PHARMACEUTICA. (From φαςμακευω, to exhibit medicines.) Pharmaceutics, or the doctrine of compounding and dosing medicines. See *Pharmacy*.

Pharmacochymia. (From φαζμακον, a medicine, and χυμια, chemistry.) Pharmacentic chemistry, or that part of chemistry which respects the preparation of medicines.

PHARMACOPCEIA. (From φαςμαιον, a medicine, and σοιεω, to make.) A dispensatory, or book of directions for the composition of medicines approved of by medical practitioners, or published by authority. The following are the most noted, viz.

P. Amstelodamensis.

P. Argentoratensis.

P. Auget oratensis.

P. Bataana.

P. Brandenburgensis.
P. Brandenburgica.

P. Bruxellensis.

P. Edinburgensis.

P. Hafniensis.

P. Londinensis.
P. Norimbergensis.

P. Pariscensis.

P. Ratisbonensis.
P. Regia.

PHARMACOPOLA. (From \$\phi agu \text{280}\text{07}, a medicine, and \$\pi \omega \text{280}\text{280}\text{, to sell.}) An apothecary, or vender of medicines.

PHARMACOPOLIUM. (From φαςμακον, a medicine, and σωλεω, to sell.) A druggist's or apothecary's shop.

PHARMACOPSIA. (From paguanov, a medicine, and meous, a potion.) A liquid medicine.

PHARMACOTHECA. (From φαζμακόν, a medicine, and τιθημι, to place.) A medicine-chest.

PHARMACY. The art of preparing remedies for the treatment of diseases.

The articles of the Materia Medica, being generally unfit for administration in their original state, are subjected to various operations, mechanical or chemical. by which they become adapted to this purpose. Herein consists the practice of pharmacy, which therefore requires a previous knowledge of the sensible and chemical properties of the substances operated on. The qualities of many bodies are materially changed by heat, especially in conjunction with air and other chemical agents; the virtues of others reside chiefly in certain parts, which may be separated by the action of various menstrua, particularly with the assistance of heat; and the joint operation of remedies on the human body is often very different from what would be anticipated, from that which they exert separately; hence, in the preparations and compositions of the Pharmacopæias, we are furnished with many powerful as well as elegant forms of medi-

Pharringæus. (From φαςυγξ, the pharryux.) Belonging to or affecting the pharrynx; thus cynanche pharyngæa, &c.

PHARYNGETHRON. paguy sedgev. The

pharynx, or fauces.

PHARINGOSTAPHYLINUS. A muscle originating in the pharynx and terminating in the septum, above the uvula.

PHARYNGOTOMIA. (From φαςυγέ, the pharynx, and τεμνω, to cut.) The opera-

tion of cutting the pharynx.

PHARYNX.  $(A\pi_0 \tau 8 \phi \epsilon g \epsilon \omega)$ , because it conveys the food into the stomach.) The muscular bag at the back part of the mouth. It is shaped like a funnel, adheres to the fauces behind the larynx, and terminates in the æsophagus. Its use is to receive the masticated food, and to convey it into the æsophagus.

Phaseolus vulcaris. (From φασηλος, a little ship, or galliot, which its pods were supposed to resemble.) The systematic name of the kidney-bean. See Bean,

kidney.

Phasganium. (From φασγανον, a knife; so called because its leaves are shaped like a knife, or sword.) The herb sword-grass.

PHATNIUM. (From parvn, a stall.) The socket of a tooth.

PHELLANDRIUM AQUATICUM. (Phellandrium; from \$\phi\_{\phi\lambda}\epsilon\_{\text{s}}\$, the cork-tree, and and \$\phi\_{\phi\lambda}\epsilon\_{\text{s}}\$ male; so called because it floats upon the water like cork.) The systematic name of the water-fennel. See Faniculum aquaticum.

PHEMOS. (From φιμοω, to shut up.) A

medicine against a dysentery.

PHILADELPHUS. (From φίλεω, to love, and αθελφος, a brother; so called because, by its roughness, it attaches itself to whatever is near it.) See Aperine.

PHL PIII

Philantheores. (From φιλεω, to love, In some it is owing to gonorrhæa, where and ανθζωτος, a man; so called from its the matter lodged between the prepuce uses.) I. Medicines relieving the pain of and the glans occasioned the same excorithe stone.

sticks to the garments of those who touch

it. See Aperine.

Philonium. (From Philo, its inventor.) A warm opiate.

l'HILTHUM. (From φιλεω, to love.) 1. A philtre, or imaginary medicine, to excite

2. The depressure on the upper lip. where lovers salute.

PHILYRIA. (The name of the daughter

ly.) Mock privet.

PHIMOSIS. (From φιμω, to bind up.) A constriction or straitness of the extre- φλεψ, a vein, and τεμιω, to cut.) The mity of the prepuce, which, preventing the glans from being uncovered, is often the occasion of many troublesome complaints. It may arise from different causes both in children and grown persons. Children have naturally the prepuce very long; and as it exceeds the extremity of the glans, and is not liable to be distended, it is apt to contract its orifice. This often occasions a lodgment of a small quantity of urine between that and the glans, which if it burn.) An inflammation grows corrosive, may irritate the parts so PHLEGMASIA DOL as to produce an inflammation. In this case, the extremity of the prepuce becomes more contracted, and consequently the urine more confined. Hence the whole inside of the prepuce excoriates and suppurates; the end of it grows thick and swells, and in some months becomes cal-At other times it does not grow thick, but becomes so strait and contracted as hardly to allow the introduction of a probe. The only way to remove this disorder is by an operation. A phimosis may affect grown persons from the same cause as little children; though there are some grown persons who cannot uncover their glans, or at least not without pain, and yet have not the extremity of the prepuce so contracted as to confine the urine from passing, we notwithstanding find them sometimes troubled with a phimosis, which might be suspected to arise from a venereal taint, but has in reality, a much more innocent cause. There are, we know, sehaceous glands situated in the prepuce, round the corona, which secrete an unctuous humaur, which sometimes becomes acrimonious, irritates the skin that covers the glans, and the irritation extending to the internal membrane of the prepuce, they both become inflamed, and yield a purulent serum, which cannot be discharged, because the glans is swelled, and monly begins with coldness and rigors; the orifice of the prepuce contracted. We these are succeeded by heat, thirst, and find also some grown persons, who, though other symptoms of pyrexia; and then pain, they never uncovered the glans, have been stiffness, and other symptoms of topisubject to phimosis from a venereal cause. cal inflamination supervene. Sometimes

ation as the discharge before mentioned 2. The herb goose-grass, because it from the sebaceous glands. In others, it proceeds from venereal chancres on the prepuce, the glans, or the frænum; which producing an inflammation either on the prepuce or glans, or both, the extremity of the fore-skin contracts, and prevents the discharge of the matter. The parts, in a very little time, are greatly tumefied, and some times a gangrene comes on in less than two days.

Phlebornhagia. (From φλεψ, a vein, of Chiron, who first applied it medicinal- and gnavous, to break out.) A rupture of

PHLEBOTOMY. (Phlebotomia; from opening of a vein.

Phleom. (From pleyw, to burn, or to excite.) In chemistry it means water from distillation, but, in the common acceptation of the word, it is a thick and tenacious mucus secreted in the lungs.

Phleemagoga. (From oxeyuz, phlegm, and aya, to drive out.) Medicines which promote the discharge of phlegm.

PHLEGMASIA. (From preyer, to

PHLEGMASIA DOLENS. A disease noticed by some of the French writers, under the name of L'enflure des jambes et des cuistes de la femme accouchée; whilst others have called it depôt du lait, from its supposed cause. By the Germans it is ealled Œdema lacteum, and by the English the white leg. This disease principally affects women in the puerperal state; in a few instances it has been observed to attack pregnant women; and, in one or two cases, nurses on losing their children, have been affected by it. Women of all descriptions are liable to be attacked by it during and soon after childhed; but, those whose limbs have been pained or anasareous during pregnancy, and who do not suckle their offspring, are more especially subject to it. It has rarely occurred oftener than once to the same female. It supervenes to easy and natural, as well as to difficult and preternatural, births. It sometimes makes its appearance in twenty-four or forty-eight hours after delivery, and at other times, not till a month or six weeks after; but in general, the attack takes place from the tenth to the sixteenth day of the lying-in. It has in many instances, attacked women who were recovering from puerperal fever; and, in some cases, has supervened, or succeeded to thoracie inflammation. It not uncom-

Upon other oceasions, the to-full formation. In most instances, it arrives pical affection is neither preceded by puer- at double the natural size, and in some peral fever, nor rigors, &e. but soon after cases at a much greater. In lax habits, and it has taken place, the pulse becomes more in patients whose legs have been very much frequent, the heat of the body is increased, affected with anasarea during pregnancy. and the patient is affected with thirst, the swelling takes place more rapidly than head ache, &c. The pyrexia is very vari- in those who are differently eircumstanous in degree in different patients, and ced; it sometimes arrives, in the former sometimes assumes an irregular remittent class of patients, at its greatest extent in or intermittent type. The complaint generally takes place on one side only at first, and the part where it commences is various; but it most commonly begins in the upper part of the limb, and descending to lumbar, hypogastrie, or inguinal region. on one side, or in the hip, or top of the thigh, and corresponding labium pudendi. In this case the patient first perceives a sense of pain, weight, and stiffness, in some of the above-mentioned parts, which are increased by every attempt to move the pelvis, or lower limb. If the part be carefully examined, it generally is found rather fuller or hotter than natural, and tender to the touch, but not discoloured. The pain increases, always becomes very se- eight, the febrile symptoms diminish, and vere, and, in some cases, is of the most exerueiating kind. It extends along the thigh, and when it has subsisted for some time longer or shorter in different patients, the top of the thigh and the labium pudendi become greatly swelled, and the pain is then sometimes alleviated, but accompanied with a greater sense of distention. The pain next extends down to the knee, and is generally the most severe on the inside and back of the thigh, in the direction of the internal cutaneous and the crural nerves; when it has continued for some time, the whole of the thigh becomes swelled, and the pain is somewhat relieved. The pain then extends down the leg to the foot, and is commonly the most severe in the direction of the posterior tibial nerve; after some time, the parts last attacked begin to swell, and the pain abates in violence, but is still very considerable, especially on any attempt to move the limb. The extremity being now swelled throughout its whole extent, appears perfectly or nearly uniform, and it is not perceptibly lessened by an horizon- reduced, and the limb feels stiff, heavy, betal position, like an adematose limb. It numbed and weak. When the finger is is of the natural colour, or even whiter; is pressed strongly against it for some time, hotter than natural; excessively tense, and in different points, it is found to be less exquisitely tender when touched. When elastic than at first, in some places retainpressed by the finger in different parts, it ing the impression of the finger for a is found to be elastic, little, if any, impres- longer, in other places for a shorter time, sion remaining, and that only for a very or scareely at all. And, if the limb be short time. If a puncture, or incision, be suffered to hang down, or if the patient made into the limb, in some instances, no walk much, it is found to be more swelled fluid is discharged; in others, a small in the evening, and assumes more of an quantity only issues out, which eoagulates odematose appearance. In this state the soon after; and in others, a larger quan-limb continues for a longer or shorier tity of fluid escapes, which does not eoa- time, and is commonly at length reduced gulate; but the whole of the effused mat- wholly, or nearly to the natural size. ter cannot be drawn off in this way. The

twenty-four hours, or less, from the first attack.

Instead of beginning invariably at the the lower, this complaint has been known to begin in the foot, the middle of the leg, the ham, and the knee. In which soever of these parts it happens to begin. it is generally soon diffused over the whole of the limb, and, when this has taken place, the limb presents the same phenomena, exactly, that have been stated above, as observable when the inguen, &c. are first affected.

After some days, generally from two to the swelling, heat, tension, weight, and tenderness of the lower extremity, begin to abate, first about the upper part of the thigh, or about the knee, and afterwards in the leg and foot. Some inequalities are found in the limb, which, at first, feel like indurated glands, but, upon being more nicely examined, their edges are not so well defined as those of conglobate glands; and they appear to be occasioned by the effosed matter being of different degrees of consistence in different points. The conglobate glands of the thigh and leg are sometimes felt distinctly, and are tender to the touch, but are seldom materially enlarged; and as the swelling subsides, it has happened, that an enlargement of the lymphatie vessels, in some part of the limb, has been felt, or been supposed to be

The febrile symptoms having gradually disappeared, the pain and tenderness of the limb being much relieved, and the swelling and tension being eonsiderably diminished, the patient is debilitated and much

Hitherto the disease has been described

PIIO

as affecting only one of the inferior extremities, and as terminating by resolution, or the effusion of a fluid that is moved by the absorbents; but, unfortunately, it sometimes happens, that after it abates in one limb, the other is attacked in a similar way. It also happens, in some eases, that the swelling is not terminated by resolution; for sometimes a suppuration takes place in one or both legs, and ulcers are formed which are difficult to heal. In a few eases, a gangrene has supervened. In some instances, the patient has been destoyed by the violence of the disease, before either suppuration or gangrene have happened.

The predisposing canses of this disease, when it occurs during the pregnant or puerperal state, or in a short time afterwards, appear to be, 1st, The increased irritability and disposition to inflammation which prevailed during pregnancy, and in a still higher degree for some time after par-2dly, The over-distended, or returition. laxed state of the blood-vessels of the inferior part of the trunk and of the lower extremities, produced during the latter months of

utero-gestation.

Amongst the exciting causes of this discase may be enumerated, 1st, Contusions, or violent exertions of the lower portions of the abdominal and other muscles inserted in the pelvis, or thighs, or of the museles of the inferior extremities, and contusions of the cellular texture conneeted with these muscles, during a tedions labour. 2dly, The application of cold and moisture, which are known to act very powerfully upon every system in changing the natural distribution of the circulating fluids, and, consequently, in a system predisposed by parturition, may assist in producing the disease, by occasioning the fluids to be impelled, in unusual quantity, into the weakened vessels of the lumbar, hypogastric, and inguinal regions, and of the inferior extremities. Sdly, Suppression, or diminution of the lochia, and of the secretion of milk, which, by inducing a plethoric state of the sanguiferous system, may occasion an inflammatory diathesis, may favour congestion, and the determination of an unusual quantity of blood to the vessels of the parts just mentioned, and thus contribute to the production of an inflammation of these parts. 4thly, Food taken in too large quantity, and of a too stimulating quality, especially when the patient does not give suck. This cause both favours the production of plethora, and stimulates the heart and arteries to more frequent and violent action; the effects of which may be expected to be particularly felt in the lumbar, hypogastrie, or ingninal regions, and in the lower extremities, from the state of their blood-vessels. 5thly. Standing, or walking too much, before the

arteries and veins of the lower half of the body have recovered sufficiently from the effects of the distention which existed during the latter months of pregnancy. This must necessarily occasion too great a de-termination of blood to these parts, and consequently too great a congestion in them; whence they will be more stimulating than the upper parts of the body, and inflammation will sometimes be exeited in them.

From an attentive consideration of the whole of the phenomena observable in this disease, and of its remote causes and cure, no doubt remains, Dr. Hull thinks, that the proximate cause consists in an inflammatory affection, producing suddenly a considerable effusion of serum and coagulating lymph from the exhalents into the cellular membrane of the limb.

PHLEGMASIÆ. Inflammations. The second order in the class pyrexiæ of Cullen's nosological arrangement, character-

ised by pyrexia, with topical pain and inflammation; the blood, after venesection,

exhibiting a buffy coat.

PHLEGMATORRHAGIA. (From pheyma, mueus, and gnyyuui, to break out.) A discharge of thin mucous phlegm from the nose, through cold.

PHLEGMON. (From φλερω, to burn.) Phlegmone. An inflammation of a bright red colour, with a throbbing and pointed

umour, tending to suppuration.

Phlodiston. (From φλογίζω, to burn.) The inflammable principle. Staal gave this term to a principle which he imagined was pure fire, or the matter of fire fixed in combustible bodies, in order to distinguish it from fire in action, or in a state of liberty.

Phlogisticated air. See Nitrogen gas. (From φλογοω, to in-PHLOGOSIS.

flame.) Inflammation.

PHLYCTÆNÆ. (Φλαταιται, small bladders.) Phlyctis. Phlysis. Small pellucid vesicles, that contain a serous fluid. Linnæus and Vogel use this term as synonymous with hydates

Phlezacium. (From φλυζω, to be hot.) A pustule on the skin, excited by fire, or

heat. See Pustule.

PHENIX DACTYLIFERA. (Phanix; from Phanecia, its native soil.) The systematic name of the date-tree. See Dactylus.

PHOSPHATS. (Phosphas; from phosphorus.) Salts formed by the union of phosphorie acids with different bases; thus, phosphat of ammonia, phosphat of lime, &c.

PHOSPHITES. Phosphis. Salts formed by the combination of phosphorus acid with different bases; thus, aluminous phosphite, ammoniacal phosphite, &c.

Phosphorated hydrogen gas. See Hydro-

gen gas, phosphoruted.

PHOSPHORIC ACID. Acidum phosphoricum. This acid may be obtained from 4 K

bones, in the following manner:-Three and suffered to stand undisturbed; when parts of diluted sulphuric acid are to be the precipitate is fully subsided, the clear effused upon four parts of pulverised fluid is to be separated. The precipitate ashes of bones, while continually stirred. is then formed into a paste, with char-By this means the sulphuric acid com- coal powder, and the mass is to be dried bines with the calcareous earth, and disengages the phosphoric acid. The mass is then to be repeatedly washed in water, and the ley slowly evaporated: the sulphate of lime, which still adheres, will be thus gradually expelled; and at last, phosphoric acid, in a dry and vitreous form, will be obtained.

PHOSPHORUS. (From out, light, and φιζω, to carry.) Autophosphorus. Phosphorus has never been found pure in nature. It is always met with united to oxygen, or in the state of phosphoric acid. In that state it exists very plentifully, and is united to different animal, vegetable,

and mineral substances.

Properties .- Phosphorus is a flesh-coloured or yellowish semi-transparent substance, of the consistence of wax, but brittle during frost. In atmospheric air, it is luminous at common temperatures without emitting heat. It has a rough disagreeable taste, and its odour resembles that of garlic. Its specific gravity is 2.033, water being 1.000. Phosphorus crystallises in laminæ, in needles, or elongated octahedra. Exposed to the light, it becomes covered with a crust, which is first white, next orange, and at last red. It becomes liquid at a temperature of 99° Fahr. It takes fire spontaneously, and burns rapidly in the open air, at 122° Fahr. with a brilliant white flame, and becomes converted into phosphoric acid. It is volatilised at 554° Fahr. It is soluble in caustic alkalies, by the assistance of heat. Expressed and essential oils take up a small quantity, and are rendered luminous. Sulphuric ether, nitric ether, and ardent spirit, dissolve it sparingly in the cold. It combines with lime, strontia, barytes, sulphur, and with metals. It is soluble in hydrogen gas, and decomposes nitric acid, and metallic solutions. It acts strongly, and frequently like poison, on living ani-

Methods of obtaining Phosphorus.-For some time, phosphorus was made in very inconsiderable quantities, and by a tedious porating considerable quantities of urine, and decomposing them by various means.

The following processes, now employed,

are more easy and expeditions.

Giobert's Process .- According to this method, phosphorus may be obtained very economically, and without any offensive preparation. It consists in pouring a concentrated solution of nitrate of lead, by a little at a time, into a quantity of urine, until no more cloudiness is produced by a further addition of the solution. The mix- liquor. The charcoal, at an elevated tem-ture in then to be diluted with soft water.

gradually in an earthen pan, and submitted to distillation.

In this process the phosphoric acid of the urine, unites to the lead of the nitrate of lead, and the nitric acid joins to the ammonia and soda of the urine; hence phos. phate of lead, and nitrate of soda and am. monia are formed. The former, being insoluble, falls to the bottom, and the latter salt remains in the super-natant fluid. On adding charcoal to the phosphate of lead, and exposing it to a high temperature, the union is again broken; the phosphoric acid becomes decomposed, its oxygen unites to the charcoal, and forms carbonic acid gas, which flies off during the distillation; the phosphorus appears in its simple state, and the metal is left behind in the retort, together with the super-

abundand quantity of charcoal.

Nicola's Process .- Take a quantity of bones of adult animals, burn them to whiteness in an open fire, and reduce them to a fine powder. Upon three pounds of this powder, after having been put into a matrass, there may be poured two pounds of concentrated sulphuric acid of commerce; four or five pounds of water must be afterwards added by degrees, to assist the action of the acid. During the whole process, the operator must place himself and the vessel, so that the fumes of the mixture may be blown from him. The whole is then to be left in a gentle-heated sand-bath, for about twelve hours, or more, taking care to supply the loss of water which happens by evaporation. The next day, a large quantity of water must be added, the clear water afterwards decanted, and the rest strained through a cloth or sieve. The residuary matter is to be edulcorated by repeated effusions of hot water, till it passes tasteless. water which has been used to wash out the adhering acid, is mixed with the before decanted or strained liquor, and the whole fluid is gradually evaporated in a flat earthern basin, to the consistence of syrup. It is then to be mixed with an and dis. greeable process, consisting in eva- equal weight of charcoal powder, and submitted to distillation in an iron or earthen retort. Instead of applying a receiver, the neck of the retort may be immersed in a basin of water, to a small depth, and the phosphorus, as it comes over, will fall in drops to the bottom.

In this process, the sulphuric acid unites with the calcareous earth of the bones, and forms sulphate of lime; and the phosphoric acid of the bones becomes disengaged, and remains dissolved in the

phosphorus passes over.

Method of purifying Phosphorus .- Phosphorus obtained in either manner is of a dirty blackish colour, and soiled with a certain quantity of charcoal and half-burnt phosphorus, which gives it that appearance. In order to purify it, it must be put into a piece of chamois leather, and closely tied up in it. The whole is then immersed in a vessel of boiling water, the phosphorus melts, and may be pressed through the leather, taking care to keep it under the water.

It is better, however, to purify phos-

phorus by a second distillation.

Dr. Higgins purified it by means of hy-

drogen gas.

Methods of moulding Phosphorus into Cylinders.-In order to form phosphorus into sticks, a finnel with a long neck may be used, the lower orifice of which is closed with a cork; the funnel is then to be filled with water, and phosphorus put in it, and this being plunged into boiling water, the heat communicated to the funnel melts the phosphorus, which runs into the neck and acquires that form. The funnel is then removed into a vessel of cold water, and when it is thoroughly cooled, the cork is taken out and the phosphorus thrust out of its mould with a piece of wood, and then preserved in water.

Pelletier invented another method,

which is as follows:

Take a few tubes of any length, the apertures of which are of such a size that they can be exactly closed with the extremity of the finger. Melt the phosphorus in boiling water, and apply to it one of the ends of the tube, while you hold the other in your mouth; make a short inspiration, that the phosphorus may ascend a little way in the tube; stop the inspiration when the phosphorus has risen a sufficient height, and close the extremity of the tube with the fore finger, and immerse it in a basin of cold water. The phosphorus will soon become fixed, and by a slight shake may be separated from the tube.

The earliest account we have concerning the medicinal use of phosphorus, is in the seventh volume of Haller's Collection of Theses, relating to the history and cure of diseases. The original dissertation is entitled, De Phosphori Loco Medicamenti adsumpti virtute medica, aliquot casibus singularibus confirmata, Auctore J. Gabi Mentz. There are three cases of singular cures performed by means of phosphorus, narrated in this thesis; the history of these cases and cures was sent to Dr. Gabi

Mentz, by his father. The first instance is of a man who laboured under a putrid fever; for whom the best alexipharmic medicines, as they are called, together with a proper regimen,

and carbonic acid gas is formed, and were prescribed. A diarrhæa, however, ensued, accompanied with great anxiety about the præcordia, delirium, and general prostration of the powers of life. Proper remedies were tried to stop the diarrhæa, and check the disease, but in vain. three days the patient had been insensible and exhausted. In this extremity the physician had recourse to phosphorus; two grains of which were exhibited, together with a sufficient quantity of theraica, to make them into a bolus. This occasioned a gentle sweat, and general quiet. dose was twice repeated in the evening, and again towards morning, with the addition of another grain. The sweat became copious, and the memory and the use of the external senses were restored. The patient, thus revived, was afterwards completely re-established by other remedies.

> The second case, is that, of a man who laboured under a bilious fever. Although various remedies appear to have been judiciously employed, yet the disease gained ground, until at last the patient was almost quite exhausted. Three grains of phosphorus were exhibited at eleven o'clock in the forenoon, which produced a little quiet; but the patient became so thirsty that he could not refrain from drinking. After this he was quiet for two hours, and a profuse sweat broke out all over his body. The physician seeing this, ordered him another dose in the evening. He slept and perspired the whole evening, and by means of proper remedies, was afterwards completely cured.

> The third case is entitled a malignant catarrhal fever, with petechia. It seems to have been the common typhus putridus of Cullen, accompanied with cough and catarrhal symptoms in the beginning. We are informed, that on the third day of the disease, the patient was deprived of the use of his external senses; that he became delirious and exceedingly exhausted. Two grains of phosphorus were given to him at two o'clock, and two more in the evening, which restored him to his senses, and occasioned a copious sweat. Proper remedies were afterwards employed, which ac-

complished his recovery.

Dr. Mentz appears to have been one of the first practitioners who tried this heroic remedy internally. Dr. Morgenstern and Dr. Hatman seem both to have afterwards

employed it.

The following twelve cases, relating to this interesting subject, are translated from a thesis which is very little known in this country. It is the inaugural dissertation of one Dr. Wolff, who graduated at Gottingen in the year 1791: and who states that the cases are extracted from the private diary of his father, a physician of eminence in Poland, who practised physic with to receive some antiphlogistic and emol-

of thirty years.

Case I-In the month of August, 1763. I was called to a woman twenty-five years old, whom I found in a state of low delirium. Her pulse was small, weak, and tremulous, almost vanishing, as it were, under the finger. Her whole chest and arms were disfigured with livid spots. Her neighbours and attendants informed me that she had been seized with a fever about cleven days before I saw her : and that she had been attended by some ignorant practitioner, who, finding that his remedies did not succeed, had deserted her the day before, declaring that God alone could cure

The case appeared to me one of those desperate states of disease, in which a practitioner either ought to refrain from doing any thing, or to make trial of some new, bold, and powerful remedy, which might act as an uncommon stimulus to the nerves, and rouse their suppressed energy. Such a remedy I expected to find in phosphorus, and accordingly I ordered my patient five drops of its solution, in æther, which contained three grains of phosphorus. They were exhibited in a spoonful of Rhenish wine, and the patient swallowed a few cupfuls of an infusion of the flores tilizafter them. I visited the patient three hours afterwards, and, not finding any change, I repeated the dose. Two hours were scarce elapsed when the pulse began to rise, and the whole body to be diffused with an equal heat; immediately afterwards, the pulse became undulatory, a breathing sweat (sudor halituosus) broke out, and at the same time the delirium subsided.

I exhibited a third dose at the end of sixteen hours; a number of red spots then appeared on the skin, and the patient complained very much of a sense of oppression and pain at the præcordia, and in the abdomen. These symptoms I endeavoured to allay by diluents and frequent emollient clysters, which brought away a great quantity of foul faces. The Peruvian bark completed the cure.

Case II .- A young woman, twenty-two years of age, was, for the first time, delivered of a healthy child. She recovered perfectly well for the first nine days; but being then greatly frightened by some sudden noise in the house, she was seized with a chilly fit, afterwards with flushes of heat, and soon became delirious. I was called to her on the third day, after various remedies had been tried in vain by another physician. Finding that she had a hard pulse, with great oppression in her chest, and a foul tongue, I ordered her to be blooded, to take a solution of Glauber's salts, and

great success and reputation for upwards lient clysters. Theother physician strongly opposed this advice, contending strenuously for his heating diaphoretic plan; and I therefore returned home. He continued to administer his alexipharmics and cardiac remedies to the unhappy patient. Three days elapsed before I heard any thing of her; but some of her friends then waited on me, entreating me with great earnestness to visit her, as her physician had deserted her, declaring that it was impossible for any one to save her.

I found her with a tremulous intermittent pulse, cold extremities, and wandering in her intellects. Of the solution of phosphorus I immediately gave her five drops, in a little Rhenish wine; and in about two hours after, an equal degree of heat diffused itself over her body, and her senses returned. Upon repeating the dose. a sweat broke out, which relieved her so much that I afterwards could proceed with the proper remedies for the further cure

of the complaint.

Case III .- A young man, twenty two years old, was seized with a putrido-gastric fever, which was accompanied with a white miliary eruption. On the seventh day of the disease, while under the influence of a profuse sweat, he was taken from his bed, at his own desire, and had his linen changed. An hour was scarcely elapsed when he was seized with great anxiety, the miliary eroption almost totally disappeared, and he began to grow Being called to him, I gave delirious. him the solution of phosphorus, with an infusion of elder flowers and Rhenish wine. In about an hour afterwards, the sweat and eruption returned, and he was snatched from the jaws of death.

Case IV -A youth sixteen years old, was seized with a putrid fever, on the seventh day of which he was affected with diarrhœa of so severe a kind, that he had forty-eight stools in the course of a day. Being sent for the day after, I found him with an hippocratic countenance, and subsultus tendinum. Having exhibited the phosphorus twice to him, a general breathing sweat broke out, and the diarrhoa subsided. Afterwards, proper remedies were exhibited, and he was restored to health

in fifteen days.

Seven Cases .- During the years 1770 and 1771, while the war was carried on upon the borders of our remotest provinces between the Turks and Russians, a putrid fever took its rise in the camps, and spread itself to us. It was then that I ordered this divine remedy, with the happiest effects, to seven sick who laboured under the putrid fever, some of whom had eruptions, with great prostration of strength.

Case XII.—A young lady of quality,

twenty-five years old, endowed with such likely to follow the injudicious administraan exquisite degree of nervous sensibility, tion of phosphorus, cannot be impressed that she used frequently to be affected on the mind more strongly than by the rewith spasms and convulsive motions with- lation of a few cases and experiments out any apparent cause, became pregnant which are mentioned by Wackard, in the in the year 1774, which was the seventh of fourth part of his miscellaneous writings, her marriage. On the third day preced- (Vermischte Medicinche Schrifften, von ing delivery, she was seized with a disease M. A. Wackard.) Almost about the same time that Pro-

continued to take this medicine several days, upon which he became feverish, and was affected with nausea and loss of appetite. A gentle emetic was given him. Two days after this I saw him for the first time; he told me that he had been violently affected with pain in the abdomen, particularly towards the evening. He was very dry, and his eyes were yellow. When I pressed my hand on the abdomen it did not give him pain. I ordered him whey, nitre, acid drinks, cream of tartar, and clysters. The third day after this he grew worse. I happened to be out of town, and another physician was sent for, who gave him musk, and various other remedies. I visited him in the evening and found him gangrenous. His hands were applied to his head, as if he suffered acute pain there; his screams were loud and unremitting; he was delirious and spoke unintelligibly, and there was not any pulse at the wrist. He died about midnight. Upon inspecting the body, the liver appeared obstructed, and the stomach was gangrenous near the cardia. Is it not to be feared that the phosphorus had occasioned this? or was that organ. "For two hours," the Prothis the effect of a gouty or rheumatic ac- fessor observes, "I found myself extrarimony thrown upon that part? It was af- ordinarily incommoded; I drank frequentterwards remarked, that a number of peo- ly little draughts of cold water. arose and filled the apartment, had escaped from his morsel, after which he ate it greedily. His inclination to leap and run about was now uncommonly great: nothing was too high or too distant for him; but as we were afraid he might do some injury by this kind of exercise, he was dismissed the apartment. He again vomited once or twice; but since that time has remained perfectly well."

Such are the principal facts related by Weickard. We now come to the latest publication on the subject of phosphorus. It is a letter on its medicinal virtues by M. Alphonso Leroi, and is printed in the only volume of Memoirs which the Society of Emulation at Paris has yet published. One of the first experiments which M. Leroi made was upon himself; he swallowed three grains of phosphorus with some theraica. It is a wonder, he says, that he was not killed by it; for phosphorus does not require more air than is commonly contained in the stomach, in order to take fire, and burn in such a manner as to have eaten through to phosphorus that his life was saved in a The following are some experiments most malignant fever, in which the pross on dogs:-- leave many other resourses but this re"It is now," he observes, "upwards of a medy."

was enclosed in a piece of meat; the dog rus since that time. He at first prescribed smelt it, and refused to take it; it was it in the form of a lohoch. It is always therefore forced down his throat. he has intrusted the secret only to Messrs. be dangerous even to try it. Thus much Pelletier, the brothers, being warned by his own experience of the mischief which arises from giving it improperly prepared. Each pill contains the eighth of a grain of phosphorus. They are endowed with a soporific and calming property. Professor Leroi has frequently employed them in cases of rhenmatismus, in a great number of nervous diseases, pituitous diseases, and in many acute and chronic complaints. He believes that this remedy is capable of prolonging life beyond the natural period; and after having spoken of its great restorative power, he related the following case in confirmation of this opinion :-

" I was one day called to an old man, aged eighty-seven, the uncle of Madame de Fonrqueux, in whom life seemed to be almost totally extinguished. I composed for him a mixture of six ounces of different distilled aromatic waters, one ounce of oil containing three grains of phosphorus, and two ounces of syrup. Of this he took three table spoonfuls every day; and besides this, he took eight drops of volatile alkali, in a glass of sweet aromatic water, twice a day, before his meals. By these means I illuminated the dying emhers of life, and he survived seven years after an attack of weakness in which it must have appeared like madness to attempt to interfere.

"I may safely affirm, that I have been as much occupied in seeking out the cases in which this medicine proves hurtful, as in detecting those in which it is serviceable; and I can assert, not only from my own experience, but also from that of the late M Lecointre, my pupil, who was physician to the hospital at Nambouillet, that we have not found it hurtful in any one case: that it has only been useful in some, and that only in such cases in which life was already extinct is some parts of such patients as had not a sufficient portion of living principle in them to reanimate the whole frame."

Mr. Leroi affirms, that the divisibility of phosphorus is almost infinite; and, in proof of this assertion, he states, that "the body of a woman who died of a putrid fever, and who had taken one grain of phosphorus, was entirely luminous within. The hands of the late Rielle, the anatomist, who opened the body, were luminous some hours after they had been washed!!"

Upon maturely considering all the facts which have been brought forward concerning it, little room for doubt will be left in the mind, as to its uncommon powers; but, although this be granted, expe- or fence; so called from their being set rience it still wanting to point out the diseases, and various stages of disease, in which it may be employed with equal safety and utility, as also to determine

may doubtless be asserted concerning it, that it is one of the highest stimuli which we have in the catalogue of the materia medica; and that, although it is affirmed by M. Leroi, and others, to be "calming and sedative," it is only so in such cases as wine, ather, Hoffman's anodyne liquor, and opium, are also found to be calming and sedative, that is, in cases where the arterial action of the whole frame is nearly exhausted, although still quick. Every practitioner should be cautioned against exhibiting it in any inflammatory disease, where much strength exists; and in all cases, very small doses should be first exhibited, and those with the utmost circumspection.

Phosphuret. See Phosphuretum.

PHOSPHURETUM. (Phosphuretum, from phosphorus.) A combination of phosphorus not oxygenated, with different bases; as, phosphuret of copper, phosphuret of iron, &c.

РИОТОРНОВІА. (From our, light, and pose, to dread.) Such an intolerance of light, that the eye, or rather the retina, can scarcely bear its irritating rays Such patients generally wink, or close their eyes in light, which they cannot bear without exquisite pain, or confused vision. The proximate cause is too great a sensibility in the retina. The species are,

1. Photophobia inflammatoria, or dread of light from an inflammatory cause, which is a particular symptom of the internal ophthalmia.

2. Photophobia, from the disuse of light, which happens to persons long confined in dark places or prisons; on the coming out of which intolight the pupil contracts, and the persons cannot bear light. depression of the cataract occasions this symptom, which appears as though fire and lightening entered the eye, not being able to bear these stong rays of light.

3. Photophobia nervea, or a nervous photophobia, which arises from an increased sensibility of the nervous expansion and optic nerve. It is a symptom of the hydrophohia, and many disorders, both acute and nervous.

4. Photophobia, from too great light, as looking at the sun, or at the strong light of modern lamps.

PHOTOPSIA. (From que, light, and ofic, vision.) Lucid vision. An affection of the eye in which the patient perceives luminous rays, ignited lines, or corusca-

species of hamorrhages, and other symp- rosy complexion, large veins, thick upper tonis denoting extreme debility, shewing themselves; such symptoms are generally the forerunner of death. But that when the termination is favourable, the degree of typhus which succeeds it is less in proportion to the preceding excitement in synocha. Lastly, if we succeed in removing the delirium and other symptoms affecting the head, the state of the fever is found to partake of this favourable change more immediately and completely than in synocha, where, although we succeed in relieving the head-ache or delirium, the fever often suffers little abatement.

With regard to the duration of phrenitis, Eller observes, that when it proves fatal, the patient generally dies within six or seven days. In many fatal cases, however, it is protracted for a longer time, especially where the remissions have been considerable. Upon the whole, however, the longer it is protracted, providing the symptoms do not become worse, the better

is the prognosis.

PHRENETIASIS. See Phrenitis.

Phrensy. See Phrenitis.

(From pleig, a louse.) PHTHEIRIASIS. See Phthiriasis.

PHTHEIRIUM See Phtheiroctonum.

PHTHIRIASIS. (From obeig, a louse.) Morbus Pediculosus. Pediculatio. Phtheiriasis. A disease in which several parts of the body generate lice, which often puncture the skin, and produce little sordid ulcers.

PHTHEIROCTONUM. (From obeie, a louse, and areiva, to kill, because it destroys lice.) Phtheirium. The herb staphis-agra, or Staves-acre.

PHTHISIS. (From φθιω, to consume.) Tabes Pulmonalis. Polmonary consumption. A genus of disease in the class pyrexie, and order hemorrhagie of Cullen; known by emaciation, debility, cough, hectic fever, and purulent expectoration.

Species: 1. Phthisis incipiens, incipient, without any expectoration of pus.

2. Phthisis humida, with an expectoration of pus

3. Phthisis scrophulosa, from scrophulous tubercles in the lungs, &c.

4. Phthisis hemoptoica, from hæmop-

5. Phthisis exanthematica, from exanthe-

6. Phthisis chlorotica, from chlorosis.

7. Phthisis syphilitica, from a venereal ulcer in the lungs.

The causes which predispose to this disease are very numerous. The following are, however, the most general: hereditary disposition; particular formation of body, and obvious by a long neck, prominent shoulders, and narrow chest; scrophulous diathesis, indicated by a fine clear skin, fair hair, delicate

lip, a weak voice, and great sensibility; certain diseases, such as syphilis, scrophula, the small-pox, and measles; particular employments exposing artificers to dust, such as needle pointers, stone-cutters, millers, &c. or to the fumes of metals or minerals under a confined and unwholesome air; violent passions, exertions or affections of the mind, as grief, disappointment, anxiety, or close application to study, without using proper exercise; frequent and excessive debaucheries, late watching, and drinking freely of strong liquors: great evacuations, as diarrhea, diabetes, excessive venery, fluor albus, immoderate discharge of the menstrual flux, and the continuing to suckle too long under a debilitated state; and, lastly, the application of cold, either by too sudden a change of apparel, keeping on wet clothes, lying in damp beds, or exposing the body too suddenly to cool air, when heated by exercise; in short, by any thing that gives a considerable check to the perspiration. The more immediate or occasional causes of phthisis are, hæmoptysis, pneumonic inflammation proceeding to suppuration, catarrh, asthma, and tubercles, the last of which is by far the most general. The incipient symptoms usually vary with the cause of the disease; but when it arises from tabercles, it is usually thus marked: It begins with a short dry cough, that at length becomes habitual, but from which nothing is spit up for some time, except a frothy mucus that seems to proceed from the fauces. The breathing is at the same time somewhat impeded, and upon the least bodily motion is much hurried: a sense of straitness, with oppression at the chest, is experienced; the body becomes gradually leaner, and great languor, with indolence, dejection of spirits, and loss of appetite, prevail. In this state the patient frequently continues a considerable length of time, during which he is, however, more readily affected than usual by slight colds, and upon one or other of the occasions the cough becomes more troublesome and severe, particularly by night, and it is at length attended with an expectoration, which towards morning is more free and copious. By degrees the matter which is expectorated becomes more viscid and opaque, and now assumes a greenish colour and purulent appearance, being on many occasions streaked with blood. In some cases, a more severe degree of hamoptysis attends, and the patient spits up a considerable quantity of florid, frothy blood. The breathing at length becomes more difficult, and the emaciation and weakness goes on increasing. With these, the person begins to be sensible of pain in some part of the thorax, which, however, is usually

felt at first under the sternum, particularly has the appearance of a walking skeleton; on coughing. At a more advanced period his countenance is altered, his cheeks are of the disease a pain is sometimes felt on prominent, his eyes look hollow and lanone side, and at times prevails in so high guid, his hair falls off, his nails are of a a degree, as to prevent the person from livid colour, and much incurvated, and his lying easily on that side: but it more fre- feet are affected with adematous swellings. quently happens, that it is felt only on To the end of the disease the senses remain making a full inspiration, or coughing, entire, and the mind is confident and full Even where no pain is felt it often hap- of hope. It is, indeed, a happy circumpens, that those who labour under phthisis stance attendant on phthisis, that those cannot lie easily on one or other of their who labour under it are seldom apprehensides, without a fit of coughing being excited, or the difficulty of breathing being much increased. At the first commencement of the disease, the pulse is often natural, or perhaps is soft, small, and a little quicker than usual: but when the symptoms which have been commerated have subsisted for any length of time, it then some cases a delirium precedes that event, becomes full, hard, and frequent. At the same time the face flushes, particularly after eating, the palms of the hands and lungs may possibly be mistaken for purusoles of the feet are affected with burning lent matter, and may thereby give us heat; the respiration is difficult and labores rious; evening exacerbations become obvious, and by degrees, the fever assumes the hectic form. This species of fever is evidently of the remittent kind, and has exacerbations twice every day. The first occurs usually about noon, and a slight remission ensues about five in the after- the experiment to be made in the follownoon. This last is, however, soon succeeded by another exacerbation, which increases gradually until after midnight; but about two o'clock in the morning a remission takes place, and this becomes more apparent as the morning advances. During the exacerbations the patient is very sensible to any coolness of the air, and often complains of a sense of cold when his skin is, at the same time, preter- on the properties of pus, informs us of a naturally warm. Of these exacerbations, that of the evening is by far the most considerable. From the first appearance of animal muchs. The property, he obthe hectic symptoms, the urine is high coloured, and deposits a copious branny red sediment. The appetite, however, is not is, its being composed of globules, which greatly impaired, the tongue appears clean, are visible when viewed through a microsthe mouth is usually moist, and the thirst cope; whereas animal mucus, and all is inconsiderable. As the disease advances, chemical combinations of animal subthe fauces put on rather an inflamed ap-stances appear in the microscope to be pearance, and are beset with aphtha, and made up of fl kes. This property was the red vessels of the tunica adnata be- first noticed by the late Mr. John Hunter, come of a pearly white. During the exacerbations, a florid circumscribed redness to be considered as attended with much appears on each cheek; but at other times danger; but it is more so when it proceeds the face is pale, and the countenance somewhat dejected. At the commence-ment of hectic fever, the belly is usually costive; but in the more advanced stages the risk will be greater where the abscess of it, a diarrhaa often comes on, and this breaks inwardly, and gives rise to empyecontinues to recur frequently during the remainder of the disease; colliquative by the mouth. Even cases of this nature sweats likewise break out, and these alter- have, however, been known to terminate nate with each other, and induce vast in immediate death. The impending dandebility. In the last stage of the disease ger is generally to be judged of, however, the emaciation is so great, that the patient by the hectic symptoms; but more parti-

sive or aware of any danger; and it is no uncommon occurrence to meet with persons labouring under its most advanced stage, flattering themselves with a speedy recovery, and forming distant projects under that vain hope. Some days before death the extremities become cold. and continues until life is extinguished.

As an expectoration of mucus from the under a confirmed phthisis, it may not be amiss to point out a sure criterion, by which we shall always be able to distinguish the one from the other. The medical world are indebted to the late Mr. Charles Darwin for the discovery, who has directed

ing manner:

Let the expectorated matter be dissolved in vitriolic acid, and in caustic lixivium. and add pure water to both solutions. If there is a fair precipitation in each, it is a certain sign of the presence of pus; but if there is not a precipitate in either, it is

certainly mucus.

Mr. Everard Home, in his dissertation curious, and apparently a decisive mode of distinguishing accurately between pus and serves, which characterises pus, and distinguishes it from most other substances,

Pulmonary consumption, is in every case from tubercles, than when it arises in consequence either of hamoptysis, or pneumonic suppuration. In the last instance ma, than when its contents are discharged

the degree of emaciation and debility, the Linnean system. Class, Pentandria. Orcolliquative sweats, and the diarrhea. der, Monogynia. The disease has, in many cases, been PHYSALIS ALKEKENGI. Visceralis. lour, and of a consistence nearly approaching to cartilage. Although indolent sesis. A windy tumour. at first, they at length become inflamed, and lestly form little abscesses or vomica, which breaking, and pouring their contents into the bronchia, give rise to a purulent expectoration, and thus lay the foundation of phthisis. Such tubereles or vomicæ are most usually situated at the upper and back part of the lungs; but in some instances they occupy the outer part, and then adhesions to the pleura are often formed.

When the disease is partial, only about a fourth of the upper and posterior part of the lungs is usually found diseased; but in some cases life has been protracted till not one twentieth part of them appeared, on dissection, fit for performing their function. A singular observation, confirmed by the morbid collections of anatomists, is, that the left lobe is much

oftener affected than the right.

PHTHISIS ISCHIADICA. A wasting of the thigh and leg from an abscess or other cause in the hip.

PHTHISIS PUPILLE. An amaurosis.

PHTHORIA. (From ploga, an abortion.) Medicines which promote abortion.

(\$\phi\_8\$, or \$\phi\_{90}\$, from phua, Arab.) PHU. See Valeriana major.

PHYGETHLON. (From \$vo, to grow.) A red and painful tubercle in the arm pits, neck and groins.

PHYLACTERIUM. (From ρυλασσω, to preserve.) An amulet or preservative against

infection.

PHYLLANTHUS EMBLICA. The systematic name of the Indian tree from which the emblic mirobalan is obtained. .

PHYLLITIS. (From quanto, a leaf; so called because the leaves only appear.) Sce Scolopendrium.

PHYMA. (From φυω, to produce.) small tubercle on any external part of the

body.

PHYSALIS. (From ovoaw, to inflate; 30 called because its seed is contained in a kind of bladder, and alkekengi, alkakangi, Arab, the halicacabus or winter cherry.)

PHYSETER MACROSEPHALUS. (Physeter, from φυσαω, to inflate; so named from its action of blowing and discharging water from its nostrils, and macrocephalus, from μακεος, long, and κεφαλη, the head; from the length of its head.) See Ambergris.

PHYSIOGNOMY. (Physiognomia, from φυσις, nature, and γινωσκω, to know.) The art of knowing the disposition of a person

from the countenance

PHYSIOLOGY. (Physiologia, from quois, nature, and xoyos, a discourse.) The seience which treats of the actions and powers of an animated body.

Physocele. (From φυσα, wind, and απλη, a tumour.) A species of hernia, whose contents are distended with wind.

PHYSOCEPHALUS. (From φυσα, wind, and κεφαλη, the head.) Emphysema of the

head. See Pneumatosis.

PHYSOMETRA. (From ovoda, to inflate, and Metpa, the womb.) Hysterophysc. A windy swelling of the uterus. A tympany of the womb. A genus of disease in the elass cachexiæ and order intumescentiæ of Cullen; characterised by a permanent elastic swelling of the hypogastrium, from flatulent distention of the womb. It is a rare disease, and seldom admits of

PHYTEUMA. (From outeuw, to generate; so called from its great iherease and

growth.) The herb rocket.

PHYTOLACCA DECANDRIA. (Phytolacca. From outer, a plant, and hanna, gum lac; so called because it is of the colour of lacca, and decandria, from its Linnæan arrangement ) Solanum magnum virginianum rubrum Pork-physie. Pork-weed. Pokeweed. Red weed of Virginia. Red night. shade. The systematic name of the Ameriean night-shade. Solanum racemosum Americanum. In Virginia and other parts of America, the inhabitants boil the leaves, and cat them in the manner of spinach. They are said to have an anodyne quality, and the juice of the root is violently cathartic. The Portuguese

had formerly a trick of mixing the juice quality, and are deemed serviceable in lax-of the berries with their red wines, in order to give them a deeper colour; but it PIGMENTUM. (From pingo, to paint.) was found to debase the flavour. This Pigment. This name is given by anatowas represented to his Portuguese majesty, who ordered all the stems to be cut down yearly before they produced flowers, thereby to prevent any farther adulteration. rior and posterior surface of the iris, This plant has been used as a cure for caneers, but to no purpose.

PHYTOLOGY. (Phytologia. From quitor, an herb, and xoyos, a discourse.) That part of the science of natural history

which treats on plants.

PHYTOMINESALIA. (From outer, a plant, and mineralis, a mineral.) Substances of a vegetable and mineral nature; as amber

and coral.

PIA MATER. (Pia mater, the natural mother; so called because it embraces the brain, as a good mother folds herehild.) Localis membrana. Meninx tenuis. A thin membrane, almost wholly vascular, that is ccrebrum, cerebellum, medulla oblongata, and medulla spinalis. Its use appears to be, to distribute the vessels to, and contain from the surface of the body after birth is so the substance of, the cerebrum.

PICA. (Pica, the magpie; so named because it is said the magpie is subject to Picatio. Malacia. Allothis affection.) triophagia. Citta. Cissa. Longing. Depraved appetite, with strong desire for unnatural food. It is very common to pregnant women and ehlorotic girls, and by some it is said in men who labour under

suppressed hamorrhoids.

Pices. (Hittes, pitch.) The common or red fir or pitch tree is so termed. The cones, branches, and every part of the tree, affords the common resin called frankincense. See Terebinthina vulgaris.

PICHURIM. See Pecharim.

PICKIS ECHIOIDES. (From muxpos, bitter, and echioides, from exice, from exic, a viper, and edos, resemblance.) The systematic name of the common ox-tongne; the leaves are frequently used as a pot-herb by the country people, who esteem it good to relax the bowels.

PICTONIUS. (From the Piets, who were subject to this disease.) Applied to a species of colie. It should be rather ealled colica pictorum, the painter's colic, because from their use of lead they are much afflicted with it.

Piestrum. (From \( \pi\_{\alpha} \alpha\_{\alpha}\), to press.) An instrument to compress the head of a dead fixtus, for its more easy extraction from

Pig-NUT. Earth-nut. Ground-nut. The of Linnaus. Pignuts, so called because afterwards, for if the mass then become that animal is very fond of them, and will hard and dry it is unfit for that division dig with its snout to some depth for them, for which it was originally intended; and are of a dirty brown colour, a little big- this is in many instances such an objection ger than a hazel-nut, and flavoured like the to the form that it is doubtful whether for

ntists to a mucous substance found in the eye, which is of two kinds. The pigment of the iris, is that which eovers the anteand gives the beautiful variety of colour in the eyes. The pigment of the choroid membrane, is a black or brownish mucus which covers the anterior surface of the choroid membrane, configuous to the retina and the interior surface of the eiliary processes.

PILA HYSTRICIS. The bezoar hystricis. PILA MARINA. A species of alcyoni-

um found on sea-coasts amongst wrack. It is said to kill worms, and when calcined to be useful in scrophula.

Piles. See Hamorrhois.

Pile-wort. See Cheledonium minus.

PILI CONGENITI. The hair of the head, firmly accreted to the convolutions of the eyebrows, and eyelids, are so termed, be-

cause they grow in ntero.

PILI POSTGENITI. The hair which grows termed, in contradistinction to that which appears before birth; as the hair of the head, eyebrows, and eyelids.

PILOSELLA. (From pilus, hair, because its leaves are hairy.) Auricula muris. Myosotis. Mouse ear. This common plant, Meracium pilocella of Linnæus, contains a bitter lactescent juice, which has a slight degree of adstringency. The roots are more powerful than the leaves. They are very seldom used in this country.

PILULA. A pill. A small round form of medicine the size of a pea. The consistence of pills is best preserved by keeping the mass in bladders, and oceasionally moistening it, In the direction of masses to be thus divided, the proper consistence is to be lookbulbous root of the Bunium bulbocastanum ed for at first, as well as its preservation phesnut. They are said to possess a styptic the purposes of the pharmacopæia the

greater number of articles had not better be kept in powder, and their application to the formation of pills, left to extemporaneous direction.

PILULE ALOES COMPOSITE. Compound aloetic pills. " Take of Spike aloe, powdered, an ounce; extract of gentian, half an ounce; oil of caraway, forty minims; syrup, as much as is sufficient." Beat them together, until they form an uniform mass. From fif een to twenty-five grains prove moderately purgative and stomachic.

pills with myrrh "Take of spike-aloe, moval of the venereal disease, and theretwo ounces; saffron, myrrh, of each an ounce; syrup, as much as is sufficient." Powder the aloe and myrrh separately; grains of the mass contain one of mercury. then beat them all together until they form an uniform mass. From ten grains to a cellent expectorant and alterative, calcuscruple of this pill, substituted for the lated to assist the removal of dropsical pilula Ruft, prove stomachic and laxative, diseases of the chest, and asthmas attendand are calculated for delicate females, ed with visceral obstruction. epecially where there is uterine obstruction.

PILULE CAMBOGIE GOMPOSITE. Compound gamboge pills. "Take of gamboge, powdered, extract of spike aloe, powdered, compound cinnamon powder, of each a drachim; soap, two drachms." Mix the powders together; then having added the soap, beat the whole together until they are thoroughly incorporated. These pills are now first introduced in the London Pharmacopæia, as forming a more active purgative pill than the pil. aloes cum myrrha, and in this way supplying an article very commonly necessary in prac-The dose is from ten grains to a scruple.

PILULE CUPRI. An excellent tonic and diaphoretic pill, which may be given with advantage in dropsical diseases, where mercury. tonics and divretics are indicated.

PILULE FERRI CUM MYRRHA. iron and myrrh. "Take of myrrh, pow- nacez. "Take of hard opium, powdered, dered, two drachms; subcarbonate of half an ounce; hard soap, two ounces." soda, sulphate of iron, sugar, of each a Beat them together until they are thodrachm." Rub the myrrh with the sub- roughly incorporated. The dose is from carbonate of soda; add the sulphate of three to ten grains iron, and rub them again; then beat the mass contain one of opium. whole together until they are thoroughly incorporated. scruple.

PILULE GALBANI COMPOSITE. Compound galbanum pills. Formerly called pilula gunmoss. "Take of galbanum resin, an ounce; myrrh, sagapenum, of each an ounce and half; assafætida gum resin, half an ounce; syrup, as much 'as is sufform an uniform mass. . A stimulating grains to a scruple. antispasmodic and emmenagogue. From a scruple to half a drachm may be given three times a day in nervous disorders of the stomach and intestines, in hysterical affections and hypochondriasis.

PILULE HYDRARGYRI. Mercurial pills. Often from its colour called the blue pill. "Take of purified mercury, two drachms, Confection of red roses, three drachms; liquorice root, powdered a drachm " Rub the mercury with the confection, until the globules disappear; then add the li-quorice-root, and beat the whole together, until they are thoroughly incorporated.

An alterative and antivenereal pill, which mostly acts on the bowels if given PILULE ALOES CUM MYRRHA. Aloetic in sufficient quantity to attempt the refore requires the addition of opium. The dose is from five grains to a scruple. Three Joined with the squill pill, it forms an ex-

PILULE HYDRARGYRI SUBMURIATIS. Pills of submuriate of mercury. "Take of submuriate of mercury, precipitated sulphuret of antimony, of each a drachm; guaiacum gum resin, powdered, two drachms." Rub the submuriate of mercury first with the precipitated sulphuret of antimony, then with the guaiacum gum resin, and add as much copaiba as may be requisite to give the mass a proper consistence. This is intended as a substitute for the famed Plummer's pill. It is exhibited as an alterative in a variety of diseases, especially cutaneous eruptions, pains of the venereal or rheumatic kind, cancerous and schirrous affections, and chronic ophthalmia. The dose is from five to ten grains. In about five grains of the mass there is one grain of the submuriate of

PILULE SAPONIS CUM OPIO. Pills of soap Pills of and opium. Formerly called pılulæ sapo-Five grains of the

PILULE SCILLE COMPOSITE. Compound These pills answer the squill pills. "Take of squill root fresh, same purpose as the mistura ferri compo- dried and powered, a drachm; gingersita. The dose is from ten grains to one root, powdered, hard soap, of each three drachms; ammoniacum, powdered, two drachms." Mix the powders together: then beat them with the soap, adding as much syrup as may be sufficient to give a proper consistence.

An attenuant, expectorant, and diuretic pill, mostly administered in the cure of ficient." Beat them together until they asthma and dropsy. The dose is from ten

PITUITARY MEMBRANE. Membrana pituitaria. Schneiderian membrane. The mucus membrane that lines the nostrils and sinuses, communicating with the nose, is so called, because it secretes the mucus of those parts, to which the ancients have assigned the name of pituita.

PITYRIASIS. (From mirugov, bran, so named from its branny-like appearance.) A genus in the second order, or scaly diseases, of Dr. Willan's cutaneous dis-The pityriasis consists of irregular patches of small thin scales, which repeatedly form and separate, but never collect into crusts, nor are attended with redness or inflammation, as in the lepra and scaly tetter. Dr. Willan distinguishes pityriasis over the sternum, or along the spine of from the porrigo of the Latins, which has a more extensive signification, and comprehends a disease of the scalp, terminating in ulceration; whereas the former is, by the best Greek authors, represented as always dry and scaly. Thus, according to Alexander and Paulus, pityriasis is characterised by "the separation of slight furfuraceous substances from the surface of the body,"

The pityriasis versicolor is not acuticular the head, or other parts of the body, The pityriasis versicolor is not a cuticular without ulceration." Their account of disease; for when the cuticle is abraded this appearance is conformable to expe- from any of the patches, the sallow colour rience; and the two varieties of it which remains as before in the skin or retemuthey have pointed out may be denominate cosum. PLACEBO. I will please: an epithet given to any medicine adapted more to please

than benefit the patient.

PLACENTA. (From Thanks, a cake, so called from its resemblance to a cake.) The placenta is a circular, flat, vascular, and apparently fleshy substance, different in its diameter in different subjects, but usually extending about six inches, or upwards, over about one-fourth part of the outside of the ovum in pregnant women. It is more than one inch in thickness in the middle, and becomes gradually thinner towards the circumference from which the membranes are continued. The placenta is the principal medium by which the communication between the parent and child is preserved; but though all have allowed the importance of the office which it performs, there has been a variety of opinions on the nature of that office, and of the manner in which it is executed.

That surface of the placenta which is attached to the uterus by the intervention of the connecting membrane, is lobulated and convex; but the other, which is covered with the amnion and chorion, is concave and smooth, except the little eminences made by the blood-vessels. It is seldom found attached to the same part of the uterus in two successive births; and, though it most frequently adheres to the anterior part, it is occasionally fixed to any other, even to the os uteri, in which state it becomes a cause of a dangerous hæmorrhage at the time of parturition. The placenta is composed of arteries and veins, with a mixture of pulpy or cellular substance. Of these there are two orders, very curiously interwoven with each other. The first is a continuation of those from the funis, which ramify on the internal surface of the placenta, the arteries running over the veins, which is a circumstance peculiar to the placenta; and then, sinking into its substance, anastomose and divide into mnumerable small branches. The second order proceeds from the uterus; and these ramify in a similar manner with those from the funis, as appears when a placenta is injected from those of the parent. The veins, in their ramifications, accompany the arteries as in other parts. There have been many different opinions with respect to the manner in which the blood circulates between the parent and child, during its continuance in the uterns. For a long time it was believed that the intercourse between them was uninterrupted, and that the blood propelled by the powers of the parent pervaded, by a continuance of the same compressed immediately after the birth of force, the vascular system of the fœtus;

without success to inject the whole placenta, funis and fœtus, from the vessels of the parent, or any part of the uterus, from the vessels of the funis, and it is now generally allowed, that the two systems of vessels in the placenta, one of which may be called maternal, the other fætal, are It is also admitted, that the blood of the fœtus is, with regard to its formation, increase, and circulation, un-connected with, and totally independent of the parent; except that the matter by which the blood of the fœtus is formed must be derived from the parent. It is thought that which has probably undergone some preparatory changes in its passage through the uterus, is conducted by the uterine or maternal arteries of the placenta to some cells or small cavities, in which it is deposited; and that some part of it, or something secreted from it, is absorbed by the feetal veins of the placenta, and by them conveyed to the fœtus for its nutriment. When the blood which circulates in the fœtus requires any alteration in its qualities, or when it has gone through the course of the circulation, it is carried by the arteries of the funis to the placenta, in the cells of which it is deposited, and then absorbed by the maternal veins of the placenta, and conducted to the uterus, whence it may enter the common circulation of the parent. appears, according to the opinion of Harvey, that the placenta performs the office of a gland, conveying air, or secreting the nutritious juices from the blood brought from the parent by the arteries of the uterus, and carried to the fætus by the veins of the funis, in a manner probably not unlike to that in which milk is secreted and absorbed from the breasts. The veins in the placenta are mentioned as the absorbents, because no lymphatic vessels have yet been found in the placenta.or funis; nor are there any nerves in these parts; so that the only communications hitherto discovered between the parent and child, is by the sanguineous system. The proofs of the manner in which the blood circulates between the parent and child are chiefly drawn from observations made upon the funis. When it was supposed that the child was supplied with blood in a direct stream from the parent, it was asserted that, on the division of the funis, if that part next to the placenta was not secured by a ligature, the parent would be brought into extreme danger by the hæmorrhage which must necessarily follow. But this opinion, which laid the foundation of several peculiarities in the management of the funis and placenta, is proved not to be true : for, if the funis be the child, and whilst the circulation in it but repeated attempts having been made is going on, the arteries between the part

compressed and the child throb violently, fleshy origin, from the upper and back but those between the compression and the part of the outer condyle of the os femoplacenta have no pulsation; but the vein ris. It adheres to the capsular ligament between the part compressed and the pla- of the joint, and, after running obliquely centa swells, and that part next to the fœtus becomes flaccid. But if, under the same circumstances, the funis be divided, and that part next the child be not secured, the child would be in danger of losing its nates in a long, thin, and slender tendon, life by the hæmorrhage; yet the mother would suffer no inconvenience if the other part was neglected. It is moreover proved, that a woman may die of an hæmorrhage occasioned by a separation of the placenta, and the child be nevertheless born, after either by the rupture of the vessels which pass upon its inner surface, or in any other way, the child being deprived of its proper blood, would perish, yet the parent might escape without injury. See also Secundines.

PLATA. (From mastus, broad.) shoulder-blade.

PLATIASMUS. (From Thatus, broad.) A defect in the speech in consequence of too broad a mouth.

PLATINA. A metal so called. (The name platina was given to this metal by the Spaniards from the word plata, which signifies silver in their language, by way of comparison with that metal, whose colour it imitates; or from the river Plata, near which it is found.) It exists in nature, only in a metallie state in small grains, combined with iron, copper, plumbago, &c. The largest mass of which we have heard, is one of the size of a pigeon's egg, in the possession of the Royal Society of Bergara. It is found in the parishes of Novita and Citaria, north from Choco in Peru, and near Carthagena in South America. It was

narrative of his voyage with the French academicians to Peru.

Properties .- Platina purified from all extraneous mixture is of a white colour, intermediate between that of silver and tin. It is the hardest of all metals. specific gravity being from 20.6 to 23, makes it by far the heaviest body known. It is hard, malleable, ductile, laminable like gold; but to what degree is not yet ascertained. We have seen platina drawn into a wire of a smaller diameter than the two-thousandth part of an inch. It is the most infusible of all the metals. It cannot be melted (in a considerable quantity at least,) by the most violent heat of our furnaces, but may be fused by the heat of a burning lens, or by the assistance of oxigen gas. When pure, its parts may be made to combine or weld, by hammering in a white heat; a property confined to this metal and iron. It suffers no alteration from the action of air; neither water, the eartlis, nor the salino-terrene substances have any power of re-action upon it. Potash acts upon it at high temperature. It is not oxidated when exposed red-hot to the air, for a very long time. It may however be oxidated by the galvano-electric spark, and by the nitro-muriatic acid. This acid dissolves it and assumes first a yellow and afterwards a deep orange co- of equal thickness, heat them under a lour. Platina combines with phosphorus and sulphur with considerable fa- of commerce. cility. It unites with the greater number of the metals by fusion. Of these alloys, that with copper is the most valuable, as it is ductile, susceptible of a fine polish, and does not tarnish on exposure to air; the rest of them are very little known.

Method of obtaining Platina .- The processes most commonly employed to obtain

pure platina, are as follows:

1. Take equal parts of platina in grains, and acidulous tartrite of potash, put the mixture into a well luted crucible, and expose it for two hours to a violent heat. The platina fuses, but it becomes brittle and whiter than platina is in common; then expose it to a very strong heat under a muffle, by which means all the arsenic combined with it will be disengaged, and the platina remain behind in a malleable state.

pure, by decomposing the nitro-muriatic eye.) Antimony.

formation concerning its existence in the solution of common platina, by muriate of ammonia, heating the precipitate intensely, and stamping it when of a white heat into one mass: or, by assisting the fusion with a stream of oxigen gas.

3. Jannetty's process, which is considered as the best, and which is generally used for obtaining malleable platina, is as fol-

Triturate common Platina with water, to wash off every contaminating matter that water can carry away. Mix the platina with about one-fifth part of arsenious acid and one-fifteenth part of potash; putting the whole in a proper crucible, in the following manner: having well heated the crucible and the furnace receiving it, put in one-third of the mixture, apply to this a strong heat, and add one-third more: after a renewed application of heat, throw in the last portion. After a thorough fu-sion of the whole, cool and break the mass. Then fuse it a second time, and, if necessary, even a third time, till it ceases to be magnetic. Break it into small pieces, and melt those pieces in separate crucibles, and in portions of a pound and a half of the platina to each crucible, with an equal quantity of arsenious acid and half a pound of potash. After cooling the contents of the different crucibles in a horizontal position, in order to have them throughout and hammer them into a dense mass. They are now fit to be heated in a naked fire, and hammered into bars for the purposes

Mr. Richter directs, in order to purify platina, and render it malleable, the following process: dissolve platina of commerce in nitro muriatic acid, and let fall into this solution potash, until a precipitate begins to appear; then add a solution of sulphate of potash, till the whole is Wash the precipitate till precipitated. the water that passes do not change itso colour by adding to it prussiate of potash. Dry the precipitate, and mix with it 1.5 times it weight of soda, freed from its water of crystallization; press it into a crucible, but not so as to fill it, heat it gradually, and raise the heat till it fuses.

PLATYCORIA. (From maarus, broad, and nogn, the pupil of the eye.) An enlarged

pupil.

PLATYOPHTHALMOM. (From maatus, broad, and οφθαλμος, the eye; so called 2. Platina may likewise be obtained because it is used by women to enlarge the

PLUNKET'S CANCER REMEDY. "Take crows' foot, which grows in low grounds, either common or tubulated, are employed, one handful; dogs' fennel, three sprigs; and placed in a sand-bath, or heated by both well pounded; crude brimstone in the fire of a lamp. Earthen, or coated powder, three middling thimbles full; glass retorts, are put in the naked fire white arsenic, the same quantity; incor- if necessary, they are joined with a meporated all in a mortar, and made into tallic or glass conveying pipe. When, besmall balls the size of a nutmeg, and dried sides the aëriform, other fluids are to be in the sun." These balls must be powdered collected, the middle or intermediate and mixed with the yolk of an egg, and bottle finds its use; and to prevent, after laid over the sore or cancer upon a piece cooling, the rising of the water from the of pig's bladder, or stripping of a calf trough into the disengaging vessels, the when dropped, which must be cut to the tube of safety is employed. For the exsize of the sore, and smeared with the trication of gases taking place in soluyolk of an egg. This must be applied tions, for which no external heat is recautionaly to the lips or nose lest any part quired, the bottle called disengaging botof it get down; nor is it to be laid on too tle, or proof, may be used. For receivbroad on the face, or too near the heart, ers, to collect the disengaged airs, various nor to exceed the breadth of half-a-crown; cylinders of glass are used, whether grabut elsewhere as far as the sore goes. The plaster must not be stirred until it or open at both; and, in this last case, drops off of itself, which will be in a week. Clean bandages are often to be put on.

PNEUMATIC APPARATUS. The discovery of aëriform fluids has, in modern chemistry, occasioned the necessity of some peculiar instruments, by means of which those substances may, in distillations, solutions, or other operations, be caught, collccted, and properly managed. The proper instruments for this are styled the pneumatic apparatus. Any kind of air is specifically lighter than any liquid; and therefore, if not decomposed by it, rises through it in bubbles. On this principle rests the essential part of the apparatus, adapted to such operations. Its principal part is the pneumatic trough, which is a kind of reservoir for the liquid, through which the gas is con- by a collection of air in the cellular texveyed and caused to rise, and is filled either with water or with quicksilver. Some inches below its brim an horizontal shelf is fastened, in dimension about half or the third part of the trough, and provided on its foremost edge with a row of holes, into which, from underneath, shortnecked funnels are fixed. The trough is filled with water sufficient to cover the shelf, to support the receivers, which being previously filled with water or mercury, are placed invertedly, their open end turned down upon the above-mentioned holes, through which afterwards the gases, conveyed there and directed by means of the funnels, rise in the form of air-bubbles.

In some cases the trough must be filled with quicksilver, because water decomposes some kinds of air by absorbing their basis. The price and specific gravity of that metal make it necessary to give to the quicksilver-trough smaller dimensions. It is either out in marble, or made of wood well joined. The late Karsten has contrived an apparatus, which, to the advantage of saving room, adds that of great conveniency.

To disengage gases, retorts of glass, duated or not, either closed at one end, they are made air tight by a stopper fitted by grinding. Besides these, glass bells and common bottles are employed.

To combine with water, in a commodious way, some gases that are only gradually and slowly absorbed by it, the glass apparatus of Parker is serviceable.

PNEUMATOCELE. (From Treuma, wind, and kehn, a tumour.) Any species of her-nia, that is distended with flatus.

PNEUMATOMPHALUS. (From Treuma, wind, and ompanos, the navel.) A flatulent, umbilical hernia.

PNEUMATOSIS. (From TVEUMATOW, to Emphysema. Windy swelling. inflate.) A genus of disease in the class cachexic, and order intumescentiæ of Cullen, known ture under the skin, rendering it tense, elastic, and crepitating. The species of pneumatosis are:

1. Pneumatosis spontanea, without any manifest cause.

2. Pneumatosis traumatica, from a wound. 3. Pueumatosis venenata, from poisons.

4. Pneumatosis hysterica, with hysteria. PNEUMONIA. (From @rev,uwr, a lung.) Pneumonitis. Peripneumonia. Peripneumonia vera. Inflammation of the lungs. A genus of disease in the class pyrexiæ and order phlegmasie of Cullen; characterised by pyrexia, difficult respiration, cough, and a sense of weight and pam in the thorax. The species of pneumoma, according to the above nosologist, are,

The pulse not al-1. Peripneumonia. ways hard, but sometimes soft : an obtuse pain in the breast: the respiration always difficult; sometimes the patient cannot breathe, unless in an upright posture; the face swelled, and of a livid colour; the cough for the most part moist, frequently bloody.

2. Pleuri . The pulse hard: a pungent pain in one side, aggravated during the time of inspiration; an uneusiness

when lying on one side; a very painful day; but it may likewise prove fatal, by cough, dry in the beginning of the disease, afterwards moist, and frequently bloody. See Pleuritis.

With respect to pneumonia, the most general cause of this inflammation, is the application of cold to the body, which gives a check to the perspiration, and determines a great flow of the blood to the lungs. It attacks principally those of a robust constitution and plethoric habit, and occurs most frequently in the winter season and spring of the year; but it may arise in either of the other seasons, when there are sudden vicissitudes from heat to cold.

Other causes, such as violent exertions in singing, speaking, or playing on wind instruments, by producing an increased action of the lungs, have been known to Those who have occasion peripneumony. laboured under a former attack of this complaint, are much predisposed to returns of it.

The true peripneumony comes on with an obtuse pain in the chest or side, great difficulty of breathing, (particularly in a recumbent position, or when lying on the side affected,) together with a cough, dryness of the skin, heat, anxiety, and thirst. At the first commencement of the disease the pulse is usually full, strong, hard, and frequent; but in a more advanced stage it is commonly weak, soft, and often irre-In the beginning, the cough is frequently dry and without expectoration; but in some cases it is moist even from the first, and the matter spit up is various both in colour and consistence, and is often streaked with blood.

If relief is not afforded in time, and the inflammation proceeds with such violence as to endanger suffocation, the vessels of the neck will become turgid and swelled; the face will alter to a purple colour; an effusion of blood will take place into the cellular substance of the lungs, so as to impede the circulation through that organ, and the patient will soon be deprived of

If these violent symptoms do not arise, and the proper means for carrying off the cate.) inflammation have either been neglected, or have proved ineffectual, although adopt- cated. ed at an early period of the disease, a suppuration may ensue, which event is to be known by frequent slight shiverings, and an abatement of the pain and sense of fulness in the part, and by the patient not being able to lay on the side which was affected, without experiencing great uneasiness.

so as to occasion suffocation, which usually are commonly disturbed. Species: happens between the third and seventh

terminating either in suppuration or gangrene.

When it goes off by resolution, some very evident evacuation always attends it: such as a great flow of urine, with a copious sediment, diarrhoa, a sweat diffused over the whole body, or a hæmorrhage from the nose; but the evacuation which most frequently terminates the complaint, and which does it with the greatest effect. is a free and copious expectoration of thick white or yellow matter, slightly streaked with blood, and by this the dis. ease is carried of generally in the course

of ten or twelve days. Our opinion as to the event, is to be drawn from the symptoms which are present. A high degree of fever, attended with delirium, great difficulty of breathing, acute pain, and dry cough, denote great danger: on the contrary an abatement of the febrile symptoms, and of the difficulty of breathing, and pam, taking place on the coming on of a free expectoration, or the happening of any other critical evacuation, promises fair for the recovery of the patient. A termination of the inflammation in suppuration, is always to be considered as dangerous.

On dissection, the lungs usually appear inflamed, and there is often found an extravasation, either of blood, or of coagulable lymph in their cellular substance. The same appearances likewise present themselves in the cavity of the thorax and within the pericardium. The pleura, connected with the lungs, is also in an inflamed state, having its surface every where crowded with red vessels. Besides these, abscesses are frequently found in the substance of the lungs, as likewise tubercles and adhesions to the ribs are formed. A quantity of purulent mat. ter is often discovered also in the bron-

PNEUMOPLEURITIS. (From @veumay, the lungs, and wasvertes, an inflamination of the pleura.) An inflammation of the lungs and pleura.

3. Podagra retrograda. The retrocedent gout.

4. Podagra aberrans. Misplaced or wandering gont. See Arthritis.

Podaguania. (From podagra, the gout; so called because it was thought to expel the gont.) Gont-weed. A species of zgo- either whole, ulcerated, cut, or torn. podium.

PODONIETRUM, (From wee, a foot, and riale, to wash, or bathe.) A bath for the

PODOPHYLLUM. (From wes, a foot, and φυλλον, a leaf; so nanicel from its shape.)

A species of wolf's-bane.

Ponorneca. (From 885, a foot, and ribnat, to put.) A shoe, or stocking. An anatomical preparation, consisting of a kind of shoe of the scarf-skin, with the subject.

POISON. Venenum. That substance which, when applied externally, or taken into the human body, uniformly effects such a derangement in the animal economy as to produce disease, may be defined a poison. It is extremely difficult, however, to give a definition of a poison; and the above is subject to great inaccuracy. Poisons are divided, with respect to the kingdom to which they belong, into animal, vegetable, mineral, and halituous, or aërial.

Poisons are only deleterious in certain doses; for the most active, in small doses, form the most valuable medicines. There are, nevertheless, certain poisons, which are really such in the smallest quantity, and which are never administered medicinally; as the poison of hydrophobia, the plague. There are likewise substances which are innocent when taken into the stomach, but which prove deleterious when taken into the lungs, or when applied to an abraded surface; thus carbonic acid is continually swallowed with fermented liquors, and thus the poison of the viper may be taken with impunity; whilst inspiring carbonic acid kills, and the poison of the viper inserted into the flesh, often proves fatal.

Several substances also act as poisons when applied either externally or inter-

nally, as arsenic.

When a substance produces disease, not only in mankind, but in all animals, it is distinguished by the term common poison, as arsenic, sublimate, &c. whilst that which this country, promises to be as efficacious is poisonous to man only, or to animals, as those in greater repute. It has been and often to one genus, is said to be a re- given freely in phthisis pulmonalis, and, lative poison; thus aloes are poisonous to like other remedies, failed in producing a dogs and wolves; the phellandrium aqua- cure: yet, as a palliative, it claims attenticum kills horses, whilst oxen devour it tion. Its virtues are balsamic, demulcent, greedily, and with impunity. It appears, and corroborant.

in regard to their dose, the part of the body

Poisons enter the body in the following

ways:

- 1. Through the esophagus alone, or with the food.
  - 2. Through the anus by clysters.

3. Through the nostrils

4. Through the lungs with the air.

5. Through the absorbents of the skin,

Poison oak. See Rhus toxicodendron. POLEMONIUM. (From Polemon, its in-

ventor.) Wild sage. Poley mountain. See Polium creticum,

POLYGONATUM. (From @onus, many, and yovu, a joint; so named from its numerous joints or knots.) Sigillum Solomonis. Solomon's seal. The Convallaria polygonatum of Linnæus.

POLYGONUM. (From @odus, many, and yove, a joint; so named from its numerous joints.) The name of a genus of plants in the Linnaan system. Class, Octandria. Order, Trigynia. Knot-grass.

POLYGONUM AVICULARE. The systematic name of the knot-grass. See Centumnodia.

POLYGONUM BACCIFERUM. A species of equisetum, or horse-tail.

The systematic POLYGONUM BISTORTA. name of the officinal bistort. See Bistorta.

POLYGONUM DIVARICATUM. The systematic mame of the eastern buck-wheat

plant. See Buck-wheat, eastern.

POLYGONUM FAGOPYRUM. The systematic name of the buck-wheat. See Buck-

POLYGONUM HYDROPIPER. The systematic name of the poor man's pepper. See

POLYGONUM LATIFOLIUM. Common knotgrass.

POLYGONUM MAS. Common knot-grass. POLYGONUM MINUS. Rupture-wort.

POLYGONUM PERSICARIA. The systematic name of arsmart. See Persicaria.

Polygonum selenoides. Parsley break.

POLYPODIUM. (From wolve, many, and wus, a foot; so called because it has many roots.) The name of a genus of cervix, or from the lower edge of the osplants in the Linnaan system. Class, uteri. The first case is the most frequent, Cryptogamia. Order, Filices. Fern, or polypody.

POLYPUS. (From woxue, many, and wes, a foot; from its sending off many ramifications, like legs.) 1. The name of minated fleshy, hardly ever being schirrous,

a genus of zoophytes.

2. In Cullen's Nosology, a synonym with sarcoma. A kind of tumour, which is generally narrow where it originates, and then becomes wider, somewhat like a pear; which most commonly is met with in the nose, uterus, or vagina; and which received its name from an erroneous idea, that it is usually had several roots, or feet, like polypi, or zoophytes.

Polypi vary from each other according to the different causes that produce them, and the alterations that happen in them.  $\sigma\omega\mu\alpha$ , a body.) See Polysarchia. Sometimes a polypus of the nose is owing to a swelling of the pituitary membrane, σπαω, to draw.) A forcible instrument which swelling may possess a greater or less space of the membrane, as also its cellular substance, and may affect either one or both nostrils. Atothertimes, it arises from an ul- blance to a woman's hair, or because, in

of the rattlesnake milk-wort. See Seneka. nostrils. Polypuses are sometimes so soft, that upon the least touch they are lacerated, and bleed; at other times they are very compact, and even scirrhous. Some continue small a great while; others increase so fast as, in a short time, to push out at the nostrils, or extend backwards towards the throat. Le Dran mentions, that he has known them fill up the space behind the uvula, and, turning towards the mouth, have protruded the fleshy arch of the palate so far forwards as to make it parallel with the third dentes molares. There are others which, though at first free from any malignant disposition, become afterwards carcinomatous, and even highly cancerous. Of whatever nature the polypus is, it intercepts the passage of the air through the nostril, and when large, forces the septum narium into the other nostril, so that the patient is unable to breathe, unless through the mouth. A large polypus pressing in like manner upon the spongy bones, gradually forces them down upon the maxillary bones, and thus compresses and stops up the orifice of the ductus lachrymalis; nor is it impossible for the sides of the canalis nasalis to be pressed together. In which case the tears, having no passage through the nose, the eye is kept constantly watering, and the saccus lachrymalis, not being able to discharge its contents, is sometimes so much dilated as to form what is called a flat fistula. The above writer has seen instances of polypuses so much enlarged as to force down the ossa palati.

The polypus of the uterus is of three kinds, in respect to situation. It either grows from the fundus, the inside of the the last the most uncommon. Polypi of the uterus are always shaped like a pear, and have a thin pedicle. They are almost invariably of that species which is deno-

cancerous/or ulcerated.

The coagulable substance which is found in the cavities of the heart of those who are some time in articulo mortis, is impro-

perly called a polypus.

POLYSARCHIA. (From συλυς, much, and σαζξ, flesh.) Polysomatia. Obesitas. Corpulentia.. Steatites of Vogel. Troublesome corpulency, or fatness. A genus of disease in the class cachexia and order intumescentiæ of Cullen.

When the salt has been brought to the greatest state of purity, it attracts the humidity of the air, and is resolved into a liquor. In this state it is known by the very improper name of Oil of tartar per deliquium.

From all these salts, which are impure and imperfect earbonates of potash, the

pure alkalı may be extracted.

Methods of obtaining pure Potash -It has long been a des deratum with chemists to possess a method of preparing potash in a state of absolute purity; the strong tendency which it has to combination, renders this extremely difficult. The following arc the methods now made use of.

1. Bouillon la Grange's apparatus consists of several boxes of common deal. At the bottom put river-sand, which must be well washed, and over it add another stratum, but of a finer kind, and cover the whole with a cloth, besprinkled with wood-In the bottom of each box a hole is made, into which is fitted a glass tube, for the purpose of affording a passage to the liquor as it filters through the sand,

Having arranged the apparatus in this manner, take equal parts of quick-lime and pot-ash of commerce, if the lime is very caustic; but in the contrary case, it requires twenty-parts of lime to fifteen of pot-ash : put water into an iron kettle, bring it nearly to a state of chullition, and then add lime, which, by its slaking, will bring the water to that state compleiely. When it is slaked, mix the potash, and form of the whole a thick liquid, which must be suffered to cool a little. immediately throw water over it; but, to prevent the water from making holes, when added, place over it a small board, which will rise with the water.

pans, or other vessels, to receive the liquor which runs through the tubes; and, that the ley may not absorb carbonic acid from the atmosphere, the vessels must be closed with care, in such a manner as to tals, the fluid, which is very brown, is to exclude the external air. It will be neces- be decanted, and the salt, after being sary also to keep water always over the suffered to drain, must be re-dissolved in mixture, which must be collected till it passes tasteless from the tubes.

The liquors obtained are nearly of the same degree of strength till towards the end of the process; when they grow weak

suddenly

made of east-iron pots, beginning with the last portions, which are a little weaker; tions perfectly limped. These solutions and to prevent the necessity of keeping are to be preserved in well-closed bottles, the strongest a long time in contact with to defend them from the access of air.

4. If salt-petre be fused upon charcoal, the air when boiling, a strong ebullition is be precipitated.

> To obtain dry potash, pour the concentrated liquor into a small basin, and proceed with the evaporation, till a little of it, poured on an iron plate, or a marble slab,

becomes solid.

POTASSA.

Then put the concrete potash into a jar, and pour over it very strong alcohol; the potash alone dissolves in it; the sulphate and muriate of potash, with the portions of earth and even of earbonic acid, which it obstinately retains, or which it may have acquired from the air during the evaporation, remain at the bottom of the solution. Afterwards decant the pure liquor, and distil it in a recort till it becomes colourless. It must then be evaporated in a silver basin. On cooling, it crystallizes in white laminæ, which are sometimes three-tenths of an inch in length: or, instead of suffering it to crystallize, it may be evaporated to dryness.

2. Lowitz has given another method. According to this chemist, the whole of the operation for obtaining potash of the greatest purity, and without the least colour, consists in this: A lixivium of potash, freed from earbonic acid in the usual manner, is evaporated to a thick pellicle. After the cooling, the foreign salt which has crystallized is to be separated, and the evaporation of the lixivium continued in an iron pot. During this second evaporation, the pel-licle of foreign salts, particularly of earbonate of potash, which continues to be formed, must be carefully taken off with an iron skimmer. When no more pellicle is formed, and the matter ceases to boil up, it is removed from the fire, and suffered to Then pour the mixture into the boxes, and cool, continually stirred with an iron spatula. It is then to be dissolved in double the quantity of cold water, and the solution filtered, and evaporated in a glass retort, till it begins to deposit regular crys-Care must be taken to place earthen tals. If the mass should consolidate ever so little by cooling, a small quantity of water is to be added, and it must be heated again to render it fluid. After the formation of a sufficient quantity of regular crysthe same quantity of water. eanted fluid must be kept in a well-closed bottle, and suffered to become clear by subsiding during several days. It must then be decanted for a second evaporation and crystallization. The process must be To evaporate the water, use should be repeated as long as the crystals afford, with the least possible quantity of water, solu646

The greatest difficulty of this process arises from the facility with which the fluid assumes a solid form. To obviate this inconvenience, a small portion of it may be concentrated to the point at which it becomes converted into a solid mass by cooling. The saturation of a lixivium considerably evaporated, may be ascertained by throwing small pieces of this mass into it during its cooling. When these are no longer dissolved, it is a proof that it is at the required point.

With regard to the foreign salts which are mixed with the potash, the greatest portion separates by crystallization, after the first evaporation. The rest is separated during the second concentration, by the continual skimming of the pellicle. little which may remain with the potash must precipitate for want of water of solution, in a lixivium, wherein the alkali itself is no longer dissolved but by its own

water of crystallization.

Remarks.-The property of alkalies, to dissolve in highly rectified alcohol, with the exclusion of every foreign salt, would afford an excellent means of obtaining potash very pure, if their mutual action did not afford a new source of impurity. For when an alkali, absolutely pure and chrystallized, is dissolved in spirit of wine, even without heat, the fluid assumes a very brown colour, which becomes still deeper after being decanted from the saline mass.

ferent, accordingly as the crystals are form- do not yield their acid unless to barytes. ed with cold or heat. In the first case, the It changes blue vegetable colours green, crystals obtained are octahedra in groups, and possesses all the general properties of which contain 0.43 water of crystallization, alkalies. and excite, by their solution in water, even in the summer, a degree of cold very near the point of aqueous congelation. In the second case, very thin crystalline transparent blades of extraordinary magnitude are formed, which, by an assemblage of lines crossing each other in infinite directions, present an aggregate of cells or cavities, most commonly so perfectly closed that the vessel may be inverted without the escape of the smallest drop of lixivium, though sometimes included to the amount of an ounce or two. For this reason, it is necessary to break this fine crystallization, that the fluid may run off. The crystals present, in their regular formation, rectangular tetragonal blades, which, as they contain little water of crystallization, produce a considerable degree of heat when dissolved in water.

By exposing such alkaline crystals to a red heat, in a silver crucible, they become fused; and, after cooling, afford a mass as white as snow, extremely caustic and deli-

quescent.

As the crystals and the lixivium, during the length of time required to drain the salt, may frequently become charged with a portion of carbonic acid, it is advisable. in order to avoid this inconvenience as much as possible, that the lixivium, as soon as it is brought to the requisite point of concentration, should be poured into a narrow-necked bottle, and well closed therein to crystallize. After the crystals are formed, the bottle is to be reversed without opening, and kept in a temperature rather warm until the crystals are well dried. During the winter, the liquor, after the first crystallization, continues to crystallize without being submitted to a new evaporation, provided only that it be exposed to a temperature somewhat colder than that wherein the first crystals were formed.

Properties of pure Pot-ash .- Pot-ash, in a crystallized form, consists of soft, quadrangular, compressed prisms, which are extremely caustic and deliquescent. It dissolves all soft animal matters when brought into contact with it. It liquifies by a gentle heat, and rises in fumes at high temperatures. It does not unite in a direct manner with phosphorus. It easily combines with sulphur and metallic oxids. solves alumine in the humid way, and even a small quantity of silex; but it does not act on glucine, or zircon, nor on magnesia, or lime. It contracts no union with barytes. It absorbs water and carbonic acid rapidly. It fuses into glass with silex, by the aid of fire. It combines with the The crystallization of potash is very dif- acids, and forms salts, which in general

Decomposition of Potassa.

Potassa, from its analogy to ammonia, has often been conjectured to be a compound body; but nothing satisfactory had ever been proved. Its decomposition, however, has since been effected by the labours of Mr. Davy, and the discovery of its constituents will ever be regarded as the most important in chemistry. Mr. Davy was led to institute experiments, with a view to decompose the fixed alkalies by his previous discovery, that, by the powers of galvanism, the principles of bodies were separated, according to a certain law, some being attracted to the one galvanic pole, others to the other; and that the strength of these attracting forces are proportional to the energies of the opposite electricities in the galvanic circle, and to the conducting power and the degree of concentration of the substances submitted to their action.

In his first attempts, he exposed the alkali, dissolved in water, to the action of the galvanic battery, but the water alone of the solution was decomposed. Potassa, in fusion, was then placed in the galvanic circuit; a vivid light, and appearances of

the production of combustible matter oxygen. And this Mr. Davy soon con-were observed; on submitting the solid firmed, by synthetic experiments. alkali, rendered a conductor of electrici- He found that the metallic lustre of this

When the gloto the surface, was placed upon an insu- bules were placed in tubes containing lated disc of platina, connected with the atmospheric air, or oxygen gas, an abnegative side of the battery in a state of sorption of oxygen took place, and a crust intense activity; and a platina wire, com- of alkali was formed. When they were municating with the positive side, was brought in contact with the upper surface of the alkali. Under these circumstances brilliant white flame, was produced, and The potash began to fuse at both its points mass, which was found to be potassa; oxyof electrization. There was a violent effervescence at its upper surface; at the lower, or negative surface, there was no liberation of elastic fluid; but small globules having a high metallic lustre, and being precisely similar in visible characters to quicksilver, appeared; some of which burnt, with an explosion and bright flame, as soon as they were formed, and others remained, and were merely tarnished, and finally covered with a white film, which formed on their surfaces. These globules numerous experiments soon shewed to be the substance I was in search of, and a peculiar inflammable principle the basis of potash."

The platina, Mr. Davy found, had no share in its production; as it was equally produced when even charcoal, and other metals, were used for completing the electrical circuit. The phanomena too were quite independent of the presence of air.

As, in the decomposition of compound substances by galvanism, Mr. Davy had found that when combustible bases had by causing a substance to act on it having been developed at the negative side, oxy- a strong attraction for oxygen. They put gen is evolved at the positive side, it was clean iron filings into a gun barrel, bent so reasonable to conclude that this happen- that the filings in the curvature could be ed in the above experiment, and that the raised to a sufficient heat, by the barrel effervescence observed at the part of the being placed across a furnace. ty by being very slightly moistened, to inflammable substance immediately bethe galvanic action, these appearances came destroyed in the atmosphere, and a were still better marked; and it was in white crust formed upon it which was pure this way Mr. Davy succeeded in effecting potassa. This was soon dissolved by attracting humidity from the air; a new " A small piece of pure potash, which quantity was formed on the surface, until strongly heated, confined in given portions of oxygen, a rapid combustion, with a a vivid action was observed to take place. they were converted into a white and solid gen was absorbed, and nothing emitted which affected the purity of the residual air. From subsequent experiments, Mr. Davy endeavoured to determine the proportions of these elements. From the products of the combustion of the base, compared with the quantity of oxygen absorbed, he inferred taking the mean of two experiments, that potassa consists of 86.1 of base, and 13.9 of oxygen. From the results of the decomposition of water by the base, the proportions indicated were 84 of base and 16 of oxygen. The mean of these will be 85 and 15.

The decomposition of potassa may be effected, without difficulty, with a galvanic battery of not very high powers. One of 100 plates, of six inches square, is sufficient.

An important confirmation of the discovery is that which has been received from an experiment performed by Guy-Lussac and Thenard. It occurred to these chemists, that potassa might be decomposed He accordingly in the barrel are brought to a white heat, end of the tube, which is kept cold, so By these analytic experiments, there- as to condense it; a tube of safety, confore, potassa is proved to be a compound taining a little mercury, being connected of a peculiar substance, highly inflamma- with the extremity, to allow of the disen-ble, and having a metallic lustre, with gagement of any aerial matter, and at the

The base of the alkali is obtained in the form of brilliant lamina, adhering to the side of the gun-barrel. There is also found in the curvature where the filings were contained, an alloy of it with iron. According to Mr. Davy, who performed the experiment with success, the base thus obtained is rather heavier than that procured by electricity, probably from containing a little iron.

searches, as the base of potassa, Mr. Davy

has given the name of

## POTASSIUM;

the termination of this name being that assigned to metals, and this substance be-

ing presumed to be metallic.

Potassium, at the temperature of 60° of Fahrenheit, appears in the form of small globules, possessing the metallic of this substance on water, that it discolustre and opacity, and having the general appearance of quicksilver, so that by the the smallest quantity of water in other eye it is not easy to distinguish between them. At this temperature, however, it is rather imperfectly fluid, so that it does not easily recover its globular form. At 70° it is more liquid and mobile; and at the temperature of 100° is so completely so, that different globules can be easily run into one. At 50° it becomes a soft and malleable solid, which has the lustre of polished silver, and at 32° it becomes harder and brittle, displaying, when broken, a crystallized texture. Though so fusible, it is not very volatile, but requires a temperature approaching a red-heat to convert it into vapour. It condenses unchanged. It is a perfect conductor of electricity, and is also an excellent conductor

It is the lightest substance known; it is therefore lighter than ether, or alcohol Mr. Davy found that it did not even sink iron, is formed, a little sulphuretted hyin naphtha twice distilled, the specific gra-drogen being evolved. When the union is vity of which was about 770. Its specific gravity he estimates, compared with that of water, is as 6 to 10, at 62° of Fahrenheit. In its solid form it is rather heavier, but dily into combination. With moreury it still, when cooled to 40°, it swims in dis-

tilled naphtha.

Its chemical relations are not less sin-

gular than its physical properties.

without flame, at all temperatures below has less coherence; for small portions of it that of its volatilization; but, at this tem- appear like flattened spheres. When a perature, combustion of it takes place, globule is made to touch a globule about the heat is intense, and the light white and twice as large, they combine with convivid. It appears to combine with diffe- siderable heat; the compound is fluid at rent proportions of oxygen; at least an the temperature of its formation; but, oxide of it, in a lower state of oxydation when cold, it appears as a solid metal, than potassa, can be obtained. Potassium similar in colour to silver. If the quantity

is to keep it in naphtha; for, although it does not sink in that fluid, it is enveloped by a film of it, which protects it from the action of the air.

When heated in hydrogen gas, at a degree below its point of vaporization, it diminishes in volume, and the gas explodes with the production of alkaline fumes, when it is allowed to pass into the air, a portion of the potassium appears, therefore, to have been dissolved; but, by cool-To the matter discovered by these re- ing, this is in a great measure deposited, as the gas loses its property of detonating,

spontaneously.

Potassium, when brought into contact with water, decomposes it with great violence, an explosion is produced, with flame, and potassa is formed. Placed on ice, it instantly burns with a bright flame, melting the ice. So strong is the action vers, by the decomposition it produces, liquids, as in alcohol, or in ether. Potassium, thrown into solutions of the mineral acids, inflames and burns on the surface, and the compound of potassa, with the acid employed, is formed.

Potassium combines with the primary inflammables. When brought in contact with phosphorus, under exposure to air, both bodies become fluid, burn, and phosphate of potassa is formed. When the phate of potassa is formed. experiment is made under naphtha, so as to exclude the air, they combine, and form a compound less fusible that either of its ingredients. It has the lustre of po-

lished lead.

When potassium is brought in contact with sulphur in fusion, under the vapour of naphtha, they combine rapidly with the evolution of heat and light, and a grey substance, in appearance like sulphuret of effected in the atmosphere, inflammation

takes place.

With the metals, potassium enters reaproduces some singular results. When one part of it is added to eight or ten parts of mercury in volume, at 60° Fahrenheit, they constantly unite and form a substance ex-It combines with oxygen slowly and actly like mercury in colour, but which of the basis of potassa is still further increased, so as to be about one-thirtieth the Kali purum. Alkali vegetabile fixum causweight of mercury, the amalgam increases ticum. "Take of solution of potash, a in hardness, and becomes brittle. The gallon." Evaporate the water, in a clean solid amalgam, in which the basis is in the smallest proportion, seems to consist of ebullition has ceased, the potash remains in about one part in weight of base, and a state of fusion; pour it upon a clean iron seventy parts of mercury, and is very soft and malleable.

When these compounds are exposed to air, they rapidly absorb oxygen; potassa, which deliquesces, is formed, and, in a few minutes, the mercury is found pure and unaltered. When a glabule of the amalgam is thrown into water, it rapidly decomposes it, with a hissing noise; potassa is formed, pure hydrogen is discugaged, and the inercury remains free.

The fluid amalgam of mereury and potassium dissolves all the metals; and, in in water, and filter; then pour the solution this state of union, mercury acts on pla-

tina and iron.

When potassium is heated with gold, or silver, or copper, in a close vessel of pure glass, it rapidly acts upon them; and when the compounds are thrown into water, the fluid is decomposed, potassafarmed, and the metals appear to be separated un- prepared in the same manner from tartar, altered. It reduces the metallic oxides when heated with them, and when the potassium is in excess, it combines with the reduced metal. In consequence of this property, it decomposes flint glass and green glass, reducing the metallic oxides solves the glass. At a red heat, it acts even on the purest glass, attracting part of the oxygen of the alkari in the glass, the patash than the carbonic, serzes it and forming the substance which is patassium in the first degree of oxygenation.

PREGNANCY. Utero-gestation particular manner in which pregnancy takes place has hitherto remained involved in

obscurity, notwithst ading the laborious investigation of the most eminent philoso-

phers of all ages. Although pregnancy is a state which (with a few exceptions) is natural to all women, it is in general the source of many disagrecable sensations, and often the cause of diseases which might be attended with the worst consequences if not pro-

perly treated. It is now, however, universally acknowledged, that those women who bear chil- to the womb are equally ambiguous : and dren enjoy, usually, more certain health, and are much less liable to dangerous diseases, than those who are unmarried, or

who prove barren.

Signs of pregnancy—The womb has a very extensive influence, by means of its nerves, on many other parts of the body; hence, the changes which are produced on the womb has ascended into the cavity of it by impregnation, must be productive of the belly. In general, about the fourth changes on the state of the general system. month, or a short time after, the child be-

and cannot be depended on; for, as they quickening. Women, very improperly proceed from the irritation of the womb consider this sign as the most unequivocal on other parts, they may be occasioned by proof of pregnancy; for though, when it

every circumstance which can alter the natural state of that organ.

The first circumstance which renders pregnancy probable, is the suppression of the periodical evacuation, which is generally accompanied with fulness in the breasts, head-ache, flushings in the face, and heat in the palms of the hands.

These symptoms are commonly the consequences of suppression, and therefore are to be regarded as signs of pregnancy, in so far only as they depend on it.

As, however, the suppression of the periodical evacuation often happens from acchange of life in consequence of marriage, it can never be considered as an infallible

The belly, some weeks after pregnancy, becomes flat, fr m the womb sinking, and hence drawing down the intestines along with it; but this cannot be looked upon as a certain sign of pregnancy, because an enlargement of the womb from any other

Many women, soon after they are pregnant, become very much altered in their The most frequent predisposing causes of looks, and have peculiar irritable feelings, inducing a disposition of mind which renof the body, idiosyneracy, age, sex, and ders their temper easily ruffled, and incite structure of the part diseased.

an irresistible propensity to actions of an irresistible propensity to actions of which on other occasions they would be ashamed.

> In such cases, the features acquire a peculiar sharpness, the eyes appear larger, and the mouth wider than usual; and the woman has a particular appearance, which cannot be described, but with which wo-

men are well acquainted.

These breeding symptoms, as they are called, originate from the irritation produced on the womb by impregnation; and as they may proceed from any other circumstance which can irritate that organ, they cannot be depended on when the woman is not young, or where there is not a continued suppression for at least three periods.

The irritations on the parts contiguous therefore the signs of pregnancy, in the first four months, are always to be considered as doubtful, unless every one enumerated be distinctly and unequivocally

present.

From the fourth month, the signs of pregnancy are less ambiguous, especially after These constitute the signs of pregnancy, comes so much enlarged, that its motions.

The acarus scarabei begins to period. Those who are affected with it breed in the furrows of the cuticle, and the disorder becomes contagious.

2. The Prurigo formicans is a much more obstinate and troublesome disease than the foregoing. It usually affects persons of adult age, commencing at all seasons of the year indifferently; and its duration is from four months to two or three years, with occasional short intermissions papulæ are sometimes larger, sometimes more obscure, than in the preceding species; but, are, under every form, attended with an incessant, almost intolerable itching. They are diffused over the whole body, except the face, feet, and palms of the every attention to cleanliness or regimen, hands; they appear, however, in great, and multiply so rapidly that the patient est number on those parts which, from the ordinary mode of dress, are subjected petual irritation. The nits or eggs are to tight ligatures; as about the neck, deposited on the small hairs of the skin,

loins, and thighs. part of the night. The prurigo formicans is by most practitioners deemed contagious, and confounded with the itch. In make the following remarks: 1. The eruption is, for the most part, connected with internal disorder, and arises where no source of infection can be traced. 2. Persons affected may have constant intercourse with several others, and yet never communicate the disease to any of them. 3. Several persons of one family may have the prurigo formicans about the same time; but he thinks this should be referred rather to a common predisposition than to contagion, having observed that individuals of a family are often so affected, at certain seasons of the year, even when they reside

Although the prurigo formicans is never, like the former species, converted into the itch, yet it does occasionally terminate in a pustular disease, not con-

at a distance from each other.

3. Prurigo senilis. This affection does not differ much in its symptoms and external appearan es from the prorigo formicans; but has been thought by medical writers to merit a distinct consideration, on account of its peculiar inveteracy. The prurigo is perhaps aggravated, or becomes more permanent, in old age, from the dry, condensed state of the skin and cuticle, which often takes place at that papulæ on the neck, breast, and back;

in a high degree have little more comfort to expect during life, being incessantly tormented with a violent and universal itching. The state of the skin in the prurigo senilis, is favourable to the production of an insect, the pediculus huma. nus, more especially to the variety of it usually termed body-lice.

These insects, it is well known, are bred abundantly among the inhabitants of sordid dwellings, of jails, workhouses, &c. and in such situations prey upon persons of all ages indiscriminately. But in the prurigo sentlis they arise, notwithstanding endures extreme distress, from their and the pediculi are only found on the skin The itching is complicated with other or on the linen, not under the cuticle, as sensations, which are variously described some authors have represented. Itching of the Itching of the sensations become most violent, and nostrils, eye-lids, lips, or of the external usually preclude all rest during the greater ear, being generally symptomatic of other diseases, do not require a particular consideration

1. Prurigo podicis. Ascarides in the endeavouring to ascertain the justness of rectum excite a frequent itching and irri-this opinion, Dr. Willan has been led to tation about the sphincter ani, which ceases when the cause is removed by proper medicines. A similar complaint often arises, independently of worms, hamorrhoidal tumours, or other obvious causes, which is mostly found to affect persons engaged in sedentary occupations; and may be referred to a morbid state of secretion in the parts, founded, perhaps, on a diminution of constitutional vigour. The itching is not alway accompanied with an appearance of papulæ or tubercles; it it little troublesome during the day-time, but returns every night soon after getting into bed, and precludes rest for several hours. The complaint continues in this form during three or four months, and has then an intermission, till it is produced again by hot weather, fatigue, watching, or some irregularity in diet. The same disease occurs at the decline of life, under a variety of circumstances.

> Women after the cessation of the catamenia, are liable to be affected with this species of prurigo, more especially in summer or autumn. The skin between the nates is rough and papulated, sometimes scaly, and a little humour is discharged by violent friction. Along with this complaint, there is often an eruption of itching

a swelling and inflammation of one or both hairs. It is remarkable that they seldom ears, and a discharge of matter from be- or never fix upon the hairy scalp. This is cle, situated close to the forepart and sides of the lumbar vertebræ. It arises from Pseudes. the bodies of the last vertebra of the back, dinous and fleshy slips, that are gradually collected into one mass, which becomes PSEUDOBLEPSIS. (From \$\psi\outlefta\epsilon\eppilon\epsilon\eppilon\eppilon\epsilon\eppilon\ep be inserted tendinous at the bottom of the 1. Pseudoblepsis imaginaria, in which trochanter minor of the os femoris, and process. Between the tendon of this muscle and the ischium, we find a considerable patches of laminated scales, with little or bursa mucosa. This muscle, at its origin, noinflammation round them. The patches has some connexion with the diaphragm, very seldom extend to the size of a sixand likewise with the quadratus lumborum. It is one of the most powerful flexors of border, nor the oval or circular form by the thigh forwards, and may likewise assist in turning it outwards. When the inferior extremity is fixed, it may help to bend the body forwards, and in an erect posture, it greatly assists in preserving the equilibrium of the trunk upon the upper part of the thigh.

PARVUS. Pre-lumbo pubien PSOAS of Dumas. This muscle, which was first described by Riolanus, is situated upon the psoas magnus, at the anterior part of the loins. The psoas parvus arises thin and fleshy from the side of the uppermost vertebra of the loins, and sometimes also from the lower edge of the last vertebra of the back, and from the transverse processes of each of these vertebra; it then extends over part of the psoas magnus, and terminates in a thin flat tendon, which From this tendon a great number of fibres cus internus, and gradually loses itself on the fore part of the thigh. In the human body this muscle is very often wanting; but in a dog, according to Douglas, it is never deficient. Riolanus was of opinion, that it occurs oftener in men than in wobut the truth seems to be, that it is as often wanting in one sex as in the other. may help to raise the pelvis.

Psoas sive lumbaris internus. See Psoas

enagnus.

PSORA. Ywpa. Scubies. The itch. A genus of disease in the class locales and order dialyses of Cullen: appearing first on the wrists and between the fingers in small pustules with watery heads. It is

contagious.

PSORIASIS. (From Jopaw, to itch.) The disease to which Dr. Willan gives this title is characterised by a rough and scaly state of the cuticle, sometimes continuous, sometimes in separate patches, of various sizes, but of an irregular figure, and for the most part accompanied with rhagades or fissures of the skin. From the lepra it may be distinguished, not only seasons of the year, and by the disorder of the constitution with which it is usually attended. Dr. Willan gives the following

pears in small, distinct, but irregular takes place at nearly the same period, in

pence. They have neither an elevated which all the varieties of lepra are distinguished; but their circumference is sometimes angular, and sometimes goes into small serpentine processes. The scale formed upon each of them is thin, and may be easily detached, leaving a red, shining base. The patches are often distributed over the greatest part of the body, but more particularly on the back part of the neck, the breasts, arms, loins, thighs, and legs. They appear also upon the face, which rarely happens in lepra. In that situation they are red and more rough than the adjoining cuticle, but not covered with scales. The psoriasis guttata often appears on children in a sudden eruption, attended with a slight disorder of the constitution, and spreads over the body within two or three days. In adults it comis inserted into that part of the brim of the mences with a few scaly patches on the pelvis, where the os pubis joins the ilium. extremities, proceeds very gradually, and has a longer duration than in children Its are sent off, which form a thin fascia, that first occurrence is usually in the spring covers part of the psoas magnus and iliaseason, after violent pains in the head, stomach, and limbs. During the summer it disappears spontaneously, or may be soon removed by proper applications, but it is apt to return again early in the ensuing spring, and continues so to do for several successive years. When the scales have been remen; Winslow asserts just the contrary; moved, and the disease is about to go off, the small patches have a shining appearance, and they retain a dark red, inter-Its use seems to be to assist the psoas mixed with somewhat of a bluish colour, magnus in bending the loins forwards; for many days, or even weeks, before the and when we are lying upon our back, it skin is restored to its usual state. In the venereal disease there is an eruption which very much resembles the psoriasis guttata, the only difference being a slighter degree of scaliness, and a different shade of colour in the patches, approaching to a livid red, or very dark rose colour. The patches vary in their extent, from the section of a pea, to the size of a silver penny, but are not exactly circular. They rise at first very little, if at all, above the cuticle. As soon, however, as the scales appear on them, they become sensibly elevated; and sometimes the edge or circumference of the patch is higher than the little scales in its centre. This eruption is usually seen upon the forehead, breast, between the shoulders, or in the inside of the fore-arms, in the groins, about the inside of the thighs, by the distribution of the patches, but also and upon the skin covering the lower part by its cessation and recurrence at certain of the abdomen. The syphilitic psoriasis guttata is attended with, or soon followed by, an ulceration of the throat. It appears about six or eight weeks after 2 chancre has been healed by an ineffectual Psoriusis guttata. This complaint ap- course of mercury A similar appearance

some cases where no local symptoms had having less disposition than the lepra to been noticed. When a venereal sore is in a discharging state, this eruption, or other secondary symptoms, often appear much later than the period above mentioned. They may also be kept back three months, or even longer, by an inefficient applica- ing, or by the application of unguents, the tion of mereury. If no medicines be employed, the syphilitic form of the psoriasis guttata will proceed during several months, of the cuticle are hned by a slight scalithe number of the spots increasing, and ness. Should any portion of the diseased their bulk being somewhat enlarged, but without any other material alteration.

2. The Psoriasis diffusa spreads into large patches irregularly circumscribed, reddish, rough, and chappy, with scales dry scab; this is again succeeded by a interspersed. It commences, in general, with numerous minute asperities, or eleva- spreading in various directions. As the tions of the cuticle, more perceptible by complaint declines, the roughness, chaps, the touch than by sight. Upon these, small distinct scales are soon after formed, adhering by a dark central point, while their edges may be seen white and de- quires the proper texture. The duration tached. In the course of two or three of the psoriasis diffusa is from one to four weeks all the intervening cutiele becomes rough and chappy, appears red, and raised, and wrinkled, the lines of the skin sinking into deep furrows. The seales which form among them are often slight, and re- the usual periods of its return. In other peatedly exfoliate. Sometimes, without any cases, the disease, at the vernal returns, previous eruption of papulæ, a large portion of the skin becomes dry, harsh, with respect to the violence of the pre-cracked, reddish, and scaly, as above deceding symptoms. The eruption is, inscribed. In other cases, the disorder commences with separate patches of an uncertain form and size, some of them being small, like those in the psoriasis gutdually expand till they become confluent, quently on the breast, the calf of the leg, and nearly cover the part or limb affected. about the wrist, or within and a little bewise occur as a sequel of the lichen sim- lower part of the thigh, behind. It con-This transition takes place more certainly after frequent returns of the lichen. The parts most affected by psoriasis diffusa are the cheeks, chin, upper eyelids, and corners of the eyes, the temples, the external ear, the neck, the fleshy parts of the lower extremities, and the forearm, from the elbow to the back of the hand, along the supinator muscle of the radius. The fingers are sometimes nearly surrounded with a loose scaly incrustation; less frequently, on the forchead and scalp, on the shoulders, back, and loins, on the abdomen, and instep. This disease occasionally extends to all the parts aboveone place free, and appearing in others; sometimes again returning to its first situation. The psoriasis diffusa is attended with a sensation of heat, and with a very

form thick crusts. The chaps or fissures of the skin, which usually make a part of this complaint, are very sore and painful, but seldom discharge any fluid. When the seales are removed by frequent washsurface, though raised and uneven, appears smooth and shining; and the deep furrows surface be forcibly excoriated, there issues out a thin lymph, mixed with some drops of blood, which slightly stains and stiffens the linen, but soon concretes into a thin, white scaliness, gradually increasing, and scales, &c. disappear, and a new euticle is formed, at first red, dry, and shrivelled, but which, in two or three weeks, acmonths. If, in some constitutions, it does not then disappear, but becomes, to a certain degree, permanent, there is, at least, an aggravation or extension of it, about differs much as to its extent, and also deed, often confined to a single sealy patch, red, itching, and chapped, of a moderate size, but irregularly circumscribed. This solitary patch is sometimes situated on the tata, some much larger. The patches gra- temple, or upper part of the check, fre-Both the psoriasis guttata and diffusa like- low the elbow joint, but especially at the tinues in any of these situations several months, without much observable alteration. The complaint denominated with us the baker's itch, is an appearance of psorrasis diffusa on the back of the hand, commencing with one or two small, rough, scaly patches, and finally extending from the knuckles to the wrist. The rhagades, or chaps and fissures of the skin, are numerous about the knuckles and ball of the thumb, and where the back of the hand the nails crack and exfoliate superficially, joins the wrist. They are often highly in-The scaly patches likewise appear, though flamed, and painful, but have no discharge of fluid from them. The back of the hand is a little raised or tumefied, and, at an advanced period of the disorder, exhibits a reddish, glossy surface, without crusts or mentioned at the same time; but, in gene- numerous scales. However, the deep furral, it affects them successively, leaving rows of the cutiele are, for the most part, whitened by a slight scaliness This complaint is not general among bakers; that it is only aggravated by their business, and affects these who are otherwise distroublesome itching, especially at night, posed to it, may be collected from the It exhibits small, slight, distinct scales, fellowing circumstances: 1. It disappears about Midsummer, and returns in the cold bleed on stretching the fingers. A sensation does not immediately cease. The grocers' itch has some affinity with the bakers' itch, or tetter; hut, being usually a pustular belongs to another genus. Washerwomen, probably from the irritation of soap, are hable to be affected with a similar scaly disease on the hands, and arms, sometimes constitutions, proves very troublesome, and of long duration.

some cases, patches of the latter disorder on the face, scalp, or extremities, while the singular figures above described.

4. Psoriasis palmaria. One very obstinate species of tetter is nearly confined to the palm of the hand. It commences with a small, harsh, or scaly patch, which times affects the prolabinm without apgradually spreads over the whole palm, pearing on any other part of the body. and sometimes appears in a slighter degree Its characteristics are, as usual, scaliness, on the inside of the fingers and wrist. The intermixed with chaps and fissures of the surface feels rough from the detached and skin. The scales are of a considerable raised edges of the scaly laminæ; its co- magnitude, so that their edges are often lour often changes to brown, or black, as if loose, while the central points are atdirty; yet the most diligent washing pro- tached, a new cuticle gradually forms beduces no favourable effect. The cuticular neath the scales, but is not durable.

weather at the beginning of the year; 2. of heat, pain, and stiffness in the motions Persons constantly engaged in the business, of the hand, attends this complaint. It is after having been once affected with the worst in winter or spring, and occasionally eruption, sometimes enjoy a respite from disappears in autumn or summer, leaving a it for two or three years; 3. When the soft, dark-red cuticle; but many persons business is discontinued, the complaint are troubled with it for a series of years, experiencing only very slight remissions. Every return or aggravation of it is preceded by an increase of heat and dryness, disease at its commencement, it properly with intolerable itching. Shoemakers have the psuriasis palmaria locally, from the irritation of the wax they so constantly employ. In braziers, tinmen, silversmiths, &c. the complaint seems to he produced on the face and neck, which, in particular by handling cold metals. A long predisposition to it from a weak, languid, heetical state of the constitution may give effect to 3. The Psoriasis gyrata is distributed different occasional causes. Dr. Willan in narrow patches or stripes, variously has observed it in women after lying in; figured; some of them are nearly longitu- in some persons it is connected or alterdinal; some circular, or semicircular with nates with arthritic complaints. When the vermiform appendages; some are tortuous, palms of the hands are affected as above or scrpentine : others like earth worms or stated, a similar appearance often takes leeches: the furrows of the cuticle being place on the soles of the feet; but with the deeper than usual, make the resemblance exception of rhagades or fissures, which more striking, by giving to them an annusce more seem less table to form there, the feet lated appearance. There is a separation being usually kept warm and covered. Sometimes, also, the psoriasis palmaria is but no thick increstations are formed. Attended with a thickness of the prapution of these patches is tium, with scaliness and painful cracks. The uniform disposition of these patches is tium, with scaliness and painful cracks, singular; I have seen a large circular one. These symptoms at last produce a phymosituated on cach breast above the papilla; sis, and render connubial intercourse difficult or impracticable; so great, in some form, in analogous situations along the cases, is the obstinacy of them, that resides of the chest. The back is often vamedies are of no avail, and the patient riegated in like manner, with convoluted can only be relieved by circumcision. This tetters, similarly arranged on each side of affection of the praputium is not exactly the spine. They likewise appears in some similar to any venereal appearance, but cases on the arms and thinks intersecting rhangeles or fissures and indurated patches. cases, on the arms and thighs, intersecting rhagades or fissures, and indurated patches each other invarious directions. A slighter within the palm of the hand, take place kind of this complaint affects delicate young in syphilis, and somewhat resemble the women and children in small scaly circles or psoriasis palmaria. The venereal patches rings, little discoloured; they appear on the cheeks, neck, or upper part of the breast, having nearly the consistence of a soft and are mostly confounded with the herpe- corn. From the rhagades there is a slight tic, or pustular ring-worm. The psoriasis discharge, very offensive to the smell. gyrata has its remissions and returns, like The soles of the feet are likewise, in this the psoriasis diffusa; it also exhibits, in case, affected with the patches, not with rhagades. When the disease yields to the operation of mereury, the indurated porthe trunk of the body is chequered with tions of euticle separate, and a smooth new cuticle is found formed underneath. The fingers and toes are not affected with the patches, &c. in venercal cases.

5 Psoriasis labialis. The psoriasis somefurrows are deep, and cleft at the bottom the course of a few hours it becomes dry, longitudinally, in various places, so as to shrivelled, and broken; and, while it exfoliates, gives way to another layer of ten- with the disease has slept. They fall off der cutiele, which soon, in like manner, in the same proportion by day, and being perishes. These appearances should be distinguished from the light chaps and roughness of the lips produced by very cold or frosty weather, but easily removed. The psoriasis labialis may be a little aggravated by frost or sharp winds, vet it receives no material alleviation from an opposite temperature. It is not, indeed, confined within any certain limit, or period of duration, having, in several instances, been protracted through all the seasons. The under lip is always more affected than the upper; and the disease takes place more especially in those persons whose lips are full and prominent.

6. Psoriasis scrotalis. The skin of the scrotum may be affected in the psoriasis diffusa like other parts of the surface of the body; but sometimes a roughness and scaliness of the serotum appears as an independent complaint, attended with much heat, itching, tension, and redness. The above symptoms are succeeded by a hard, thickened, brittle texture of the skin, and by painful chaps or excoriations, which are not easy to be healed. This complaint is sometimes produced under the same circumstances as the prurigo scroti, and appears to be in some eases a sequel of it. A species of the psoriasis scrotalis likewise occurs in the lues venerea, but merits no particular attention, being always combined with other secondary symptoms of the disease.

7. Psoriasis infantilis. Infants between the ages of two months and two years, are oceasionally subject to the dry tetter. Ir- λεω, to wash.) A cold bath. regular, scaly patches, of various sizes, appear on the cheeks, chin, breast, back, nates, and thighs. They are sometimes red, and a little rough, or elevated; sometimes excoriated, then again covered with a thin incrustation; and lastly intersected by chaps or fissures. The general appearances nearly coincide with those of the psoriasis diffusa; but there are several peculiarities in the tetters of infants which

require a distinct consideration. 8. The Psoriasis inveterata, is characterised by an almost universal sealiness, the skin. It commences from a few ir- dentatis, recurvatis; capitulis aphyllis, have extremities. Others appear afterwards on markable smeil. The decoetion of the different parts, and, becoming confluent, seeds is recommended in hoarseness and spread at length over all the surface of the asperity of the fauces. body, except a part of the face, or sometimes the palms of the hands, and soles of so called because it irritates the nose, and the feet. The skin is red, deeply fur-rowed or wrinkled, stiff and rigid, so as Pyrethrum sylvestre. Draco sylvestris. somewhat to impede the motion of the Tarchon sylvestris. Sternutamentoria. Dra-muscles, and of the joints. So quick, cunculus pratensis. Sneeze-wort. Bastard of scales, that large quantities of them are foliis lanceolatis, acuminatis, argute serra-

confined within the linen, excite a trouble. some and perpetual i ching.

Psorica. (From Juga, the itch.) Mc.

dicines to eure the itch.

PS OROPHTHALMIA. (From Jugo, a seab, and οφθαλμος, an eye.) An inflammation of the eye-lids, attended with uleerations, which itch very much. By psorophthalmy Mr. Ware means a case, in which the inflammation of the eye-lids is attended with an ulceration of their edges, upon which a glutinous matter lodges, incrusts, and becomes hard, so that in sleep, when they have been long in contact, they become so adherent, that they cannot be separated without pain. The proximate eause is an acrimony deposited in the glands of the richds. The species of the psorophthalmia are:

1. Psorophthalmia crustosa, which forms dry or humid crusts in the margins of the

eyelids.

2. Psorophthalmia herpetica, in which small papulæ, itching extremely, and terminating in seurf, are observed.

Psychacogica. (From ψυχη, the mind, and αγω, to move.) Medicines which re-

cover in syncope or apoplexy.

PSYCHOTRIA EMETICA. (From JUXOS, cold, and Tgsque, to nourish, because it grows in cold places.) See Ipecacuanha.

PSYCHOTROPHUM. (From Juxos, cold, and τεεφω, to nourish; so called because it grows in places exposed to the cold.) The herb betony.

PSYCHROLUTRUM. (From \uxue, cold, and

Psycurica. (From ψυχω, to refrige-

rate.) Refrigerating medicines.
PSYDRACIÆ. (From ψυχος, cold.)
Red and somewhat elevated spots, which soon form broad and superficial vesicles, such as those produced by the stingingnettle, the bites of insects, &e. See Pus-

PSYLLIUM. (From JUNNOS, a flea; so called because it was thought to destroy fleas.) Pulicaris herba. Crystallion and cynomoia of Oribasius. Flea-wort seeds of this plant, Plantago psyllium of with a harsh, dry, and thickened state of Linnaus :- caule ramoso herbaceo, foliis subregular, though distinct patches on the a nauseous mucillaginous taste, and no re-

PTARMICA. (From Traigo, to sneeze; likewise, is the production and separation pellitory. Achillea ptarmica of Linnaus:found in the bed on which a person affected tis. The flowers and roots of this plant have a hot biting taste, approaching to that of pyrethrum, with which they also agree in their pharmaceutical properties. Their principal use is as a masticatory and sternutatory.

Sternutatory.

PTERIS. The name of a genus of plants in the Lannaan system. Class, Cryptoga-

mia. Order, Filices.

PTERIS AQUILINA. (From arrepore, wing; so called from the bleeness of its leaves to wings, and aquilina, from aquila, an eagle, from its resemblance to an eagle's wings.) The systematic name of the common brake, or female fern. See Felix famina.

PTEROCARPUS The name of a genus of plants in the Linnaan system.

PTEROCARPUS SANTALINUS. The systematic name of the red jaunder's tree. See Santalum rnbrum.

PTERYGIUM. (PTepug, a wing.) A membranous excrescence which grows upon the internal canthus of the eye chiefly, and expands itself over the albuquies and cornea towards the pupil. It appears to be an extension or prolongation of the fibres and vessels of the caruncula lachrymalis, or semilunar membrane, appearing like a wing. The species of pterygium are four:

1. Pterggium tenne, seu ungula, is a pellucid pellicle, thin, of a cinerition colour, and unpainful; growing out from the caruncula larrymalis, or membrana se-

mulunaris.

2. Ptergium crassum, seu pannus, differs from the ungula, by its thickness, red colour, and filmess of the red vessels on the white of the eye, and it stretches over the cornea like fasciculi of vessels.

S. Pterygium maliguum, is a pannes of various colours, panuful, various, and ari-

sing from a cancerous acrimony.

4. Pterygium pingne, seu pinguicula, is a mollicle like lard or fat, soft, without pain, and of a light yellow colour, which commonly is situated in the external angle of the eye, and rarely extends to the cornea; but often remains through life.

PTERYGO. Names compounded of this word belong to muscles which are connected with the pterygoid process of the sphænoid bone; as pterygo-pharyngeus, &c.

Pterygo-pharyngeus. See Constrictor pharyngus superior.

Pterygo-staphilinus externus. Sec Leva-

tor palati.

PTERVGOID PROCESS. (Pterygoides, from Alegos, a wing, and alos, resemblance.) A wing-like process of the sphænoid bone.

PTERYGOIDEUN OS, See Æthmoid bone. raise the PTERYGOIDEUS EXTERNUS. (Pterygoideus, from its belonging to the processus pterygoides.) Pterygoideus minor of internus. Winslow. Prepygo-colli-maxillaire of Dumas. A muscle placed, as it were, horiexternus.

zontally along the basis of the scull, between the pterygoid process and the condyle of the lower jaw. It usually arises by two distinct heads; one of which is thick, tendinous, and fleshy, from the outer wing of the pterygoid process of the os sphenoides, and from a small part of the os maxillare adjoining to it; the other is thin and fleshy, from a ridge in the tem-poral process of the sphenoid bone, just behind the slit that transmits the vessels to the eye. Sometimes this latter origin is wanting, and, in that case, part of the temporal muscle arises from this ridge. Now and then it affords a common origin to both these muscles. From these origins the muscle forms a strong fleshy belly, which descends almost transversely outwards and backwards, and is inserted tendinous and fleshy into a depression in the fore part of the conduloid process of the lower jaw, and into the anterior surface of the capsular ligament that surrounds the articulation of that bone. that part of this muscle, which is not hid by the pterygoideus internus, is covered by a ligamentous expansion, which is broader than that belonging to the pterygoideus internus, and originates from the inner edge of the glenoid cavity of the lower jaw, immediately before the styloid process of the temporal bone, and extends obliquely downwards, forwards, and outwards, to the inner surface of the angle of the jaw. When these muscles act together, they bring the jaw horizontally forwards. When they act singly, the jaw is moved forwards, and to the opposite side. The fibres that are inserted into the capsular ligament, serve likewise to bring the moveable cartilage forwards. PTERYGOIDEUS INTERNUS.

rygoidens major of Winslow. Pterygo-anguli-maxillaire of Dumas. This muscle arises tendinous and fleshy from the whole inner surface of the external ala of the pterygoid process, filling all the space bctween the two wings; and from that process of the os palati that makes part of the pterygoid fossa. From thence growing larger, it descends obliquely downwards, forwards, and outwards, and is inserted, by tendinous and fleshy fibres, into the inside of the lower jaw, near its angle. This muscle covers a great part of the pterygoideus externus; and along its posterior edge we observe a ligamentous band, which extends from the back part of the styloid process to the bottom of the angle of the lower jaw. The use of this muscle is to raise the lower jaw, and to pull it a little to one side.

PTERYGOIDEUS MAJOR. See Pterygoideus

PTERREGIDEUS MINOR. See Pterygoldeus

PTILOSIS. (From MILAOS, bald.) See Ma-

PTISANA. (From πτισσω, to decorticate, bruise or pound.) Ptissane. Barley deprived of its husks, pounded and made into balls.

PTOSIS. (From minlo, to fall.) Bletharoptosis. An inability of raising the upper, handful. eve-lid. The affection may be owing to several causes, the chief of which are a redundance of the skin on the eye-lid; a paralytic state of the levator muscle, and a spasm of the orbicularis.

PTOSIS IRIDIS. Prolapsus iridis. prolapsus of the iris through a wound of the cornea. It is known by a blackish tubercle, which prominates a little from the cornea in various forms. The species

of the ptosis of the iris are.

1. Ptosis recens, or a recent ptosis from a side wound of the cornea, as that which happens, though rarely, in or after the extraction of the cataract.

2. Ptosis inveturata, in which the incarcerated prolapsed iris is grown or attached to the wound or ulcer, and by the air has

become caltous or indurated.

PTYALAGOGA. (From Tluaxov, spittle, and ayw, to excite.) Ptyasmagoga. Medicines which promote a discharge of the saliva, or cause salivation.

PTYALISMOS. See Ptyclismus.

PTYALISMUS. (From πλυαλιζω, to spit.) A ptyalism or salivation, or increased secretion of saliva from the mouth.

PTYALUM. (From πλνω, to spit up.) The

saliva or mucus from the bronchia.

PTYASMAGOGA. (From movasma, sputum, and aya, to expel.) See Ptyalagoga.

PUBES. The external part of the organs of generation of both sexes, which are covered with hair.

PUBIS OS. A bone of the fætal pelvis. See Innominatum os.

PUDENDA. (From pudor, shame.) The

parts of generation.

PUDENDAGRA. (From pudenda, the private parts, and ayea, a seizure.) Cedma. A pain in the private parts. By some it is called the venereal disease. Others de- maculosum. Spotted lung-wort. fine it to be pain or uneasmess in the genital parts of men or women, somewhat resembling a diarrhoa, but without a dysuria. Dr. Berdoe asserts, in his Essay on the Pudendagra, that it is distinct from the venereal disease, and also, that it is proper to women, but that a woman labouring under it, can communicate some used, have no peculiar smell; but, in inflammatory symptoms to the penis of a their recent state, manifest a slightly adman who cohabits with her.

PUDENDUM MULIEBRE.

male parts of generation.

PUDICAL ARTERY. vel pudenda. Pudendal artery. A branch recommended in hemoptoes, trickling of the internal iliac distributed on the or- coughs, and catarrhal defluxions upon the gans of generation.

PUERILIS MORBUS. The epilepsy. PUERPERAL FEVER. Child-bed fe-

ver. Cullen considers this disease as a species of continued fever.

Puffball. See Lycoperdon.

PUGILLUS. (From pugnus, the fist.) Dragmis. A pugil. The eighth part of a

PULEGIUM. (From pulex, a flea; because the smell of its leaves, burnt, destroys fleas.) Pulegium regale. Pulegium latifolium glechon. Podding-grass. Com-mon pennyroyal. Mentha pulegium of Linnæus :- floribus verticillatis, foliis ovatis obtusis subcrenatis, caulibus subteretibus repentibus. This plant is considered as a carminative, stomachic, and emmenagogue; and is in very common use in hysterical disorders. The officinal preparations of pennyroyal are, a simple water, a spirit, and an essential oil.

Pulegium cervinum. Hart's pennyroyal. Mentha cervina of Linnæus. This plant possesses the virtues of pennyroyal in a very great degree; but is remarkably unpleasant. It is seldom employed but by the country people, who substitute it for

pennyroval.

PULICARIA. (From pulex, a flea; so named because it was thought to destroy fleas if hung in a chamber ) See Psyllium. PULMO. (Plin. πνευμών. Attice πλευ-

μων, unde per metathesin pulmo.) Lung.

See Lung.

PULMONARIA. (From pulme, the lungs; so called because of its virtues in affections of the lungs.) The name of a genus of plants in the Linnæan system. Order, Monogynia. Class, Pentandria. Lungwort.

PULMONARIA ARBOREA. Musus pulmona. rius quertinus. This subastringent, and rather acid plant, Lichen pulmonarius of Linnæus, was once in high estimation in the cure of diseases of the lungs, especially coughs, asthmas, and catarrhs. its virtues are similar, and in no way inferior to those of the lichen islandicus.

Symphytum PULMONARIA MACULATA. lem cowslips. Jerusalem sage. naria officinalis of Linnæus. This plant is rarely found to grow wild in England: but is very commonly cultivated in gardens, where its leaves become broader, and approach more to a cordate shape. The leaves, which are the part medicinally stringent and mucilaginous taste; hence The fe- it seems not wholly without foundation that they have been supposed to be de-Arteria pudica mulcent and pectoral. They have been lungs. The name pulmonaria, however, seems to have arisen rather from the not be too strongly recommended, and for speckled appearance of these leaves, re- this purpose it may be proper to pass them, sembling that of the lungs, than from any after they are mixed mechanically, though intrinsic quality which experience disco- a fine sieve. vered to be useful in pulmonary complaints.

Pulmonaria maculata.

Pulmonary consumption. See Phthisis. PULMONARY VESSELS. The pulmonary artery, ateria pulmonalis, arises from the right ventricle of the heart, and soon divides into the right and left, which ramify throughout the lungs, and form a beautiful net-work on the air vesicles, where they terminate in the veins, venæ fulmonales, whose branches at length form four trunks, which empty themselves into the left auricle of the heart

PULMONIA. (From pulmo, the lungs.)

An inflammation of the lungs.

PULMONICA. (From pulmo, the lungs.)

Medicines for the lungs.

Pulsatilla Nigricans. (From pulso, to beat abou; so called from its being perpetually agitated by the air.) This plant, Anemone pratensis of Linnaus:pedunculo involucrato, petalis apice reflexis, foliis bipinnatis, has been received into the Edmborgh Pharmacopæia upon the authority of Baron Stoerck, who recommended it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amanrosis, cataract, and opacity of the cornea, proceeding from vagreat service in venereal nodes, nocturnal pains, ulcers, caries, indurated glands, suppressed menses, serpiginous eruptions, melancholy, and palsy. The plant, in its recent state, has scarcely any smell; but its taste is extremely acrid, and, when chewed, it corrodes the tongue and

Pulsus. The beating of the PULSE. artery at the wrist is termed the pulse. It depends upon, and is synchronous with, that of the heart: hence physicians feel the pulse, to ascertain the quickness or tardiness of the blood's motion, the strength

of the heart, &c. Pulsilegium. (From pulsus, the pulse, and lego, to tell.) An instrument for

measuring the pulse.

PULVINAR. (From pulvis, dust or chaff, with which they are filled.) A medicated cushion.

PULVINARIUM. See Pulvinar.

PULVIS. A powder. Pulvinarium. This form of medicine is either coarse or very fine, simple or compound. In the compounded powders the intimate and complete admixture of the several ingredients, and more especially of those to which any of the more active substances, as opium, scammony, &c. are added, can-

l'ulvis aloes compositus. Compound powder of aloe. Formerly called pulvis PULMONARIA OFFICINALIS. The syste- aloes cum guaico. Pilulæ aromaticæ, pilulæ matic name of the spotted lung-wort. See de diambre. "Take of extract of spiked aloe, an ounce and half; guaiacum gum resin, an ounce; compound powder of cinnamon, haif an ounce." Powder the extract of aloe and guaincum gum resin separately: then mix them with the compound powder of cinnamon. The dose is from gr. x. to Dj. It is a warm aperient, laxative powder, calculated for the aged, and those affected with dyspeptic gout, attended with costiveness and spasmodic complaints of the stomach and bowels.

> Pulvis aloes cim canella. A cathartic, deobstruent powder, possessing stimulating and aloctic properties omitted in the last London Pharmacopæia, as rather suited to the purpose of extemporaneous prescription.

> PULVIS ALOES CUM FERRO. This possesses aperient and deobstruent virtues; and is mostly given in chlorosis and constipation. In the London Pharmacopæia this prescription is omitted for the same reason as pulvis aloes cum canella.

PULVIS ALOES CUM GUALACO. See Pulvis

aloes compositus.

PULVIS ANTIMONIALIS. Antimonial powder. "Take of sulphuret of antimony, powdered, a pound; hartshorn shavings, two pounds." Mix and throw them into a broad iron pot heated to a white heat, and stir the mixture constantly until it acquires an ash colour. Having taken it out, reduce it to powder, and put it into a coated crucible, upon which another inverted crucible, having a small hole in its bottom, is to be luted. Then raise the fire by degrees to a white heat, and keep it so for two hours. Reduce the residuary mass to a very fine powder. The dose is from five to ten grains. It is in high esteem as a febrifuge, sudorific, and antispasmodic. The diseases in which it is mostly exhibited are, most species of asthenic and exanthematous fevers, acute rheumatism, gout, diseases arising from obstructed perspiration, dysuria, nervous affections, spasms.

This preparation was introduced into the former London Pharmacopæia as a substitute for a medicine of extensive celebrity, Dr. James's powder; to which, however, the present form more nearly assimilates in its dose, and it is more manageable in its administration by the reduction of the proportion of antimony to one half.

PULVIS AROMATICUS. See Pulvis cimos momi compositue.

666

PULVIS CERUSSE COMPOSITUS. This is other diseases arising from obstructed permostly used in the form of collyrium, lo- spiration and spasm. The dose is from tion, or injection, as a mucilaginous seda- five grains to a scruple.

An antacid and adstringent powder, most-drachms; cinnamon bark, half an ounce;

acidity of the primæ viæ.

PULVIS CINNAMOMI COMPOSITUS.. Compound powder of cinnamon. Formerly called pulvis aromaticus: species aromatica: species diambræ sine odoratis. " Take of scruple. cinnamon bark, two ounces; cardamomseeds, an ounce and half; ginger-root, an mulant, antispasmodic, and emmenagogue ounce; long pepper, half an ounce." Rub powder, mostly exhibited in the dose of them together, so as to make a very fine from fifteen grains to two scruples, in powder. The dose is from five to ten uterine obstructions and hysterical affecgrains. An elegant stimulant, carmina- tions. tive, and stomachic powder.

PULVIS CONTRAYERVÆ COMPOSITUS. "Take of contrayerva root, powdered, five ounces; prepared shells, a pound and half." Mix. A febrifuge diaphoretic, mostly given in the dose of from one to two scruples

in slight febrile affections.

Pulvis cornu usti cum opio. Powder of burnt hartshorn with opium. Pulvis opiatus. "Take of hard opium, powdered, a drachm; hartshorn, burnt and prepared, an ounce; cochineal, powdered, a drachm." Mix. This preparation affords a convenient mode of exhibiting small quantities of opium, ten grains containing one of the opium. It is absorbent and anodyne.

PULVIS CRETE COMPOSITUS. Compound powder of chalk. Pulvis e bolo compositus sine opio. Species e scordio sine opio. Diascordium, 1720. "Take of prepared chalk, half a pound; cinnamon bark, four ounces; tormentill root, acacia gum, of each three ounces; long pepper, half an ounce." Reduce them separately into a very fine powder, and then mix. The dose is from 5ss. to 3i. An adstringent, carminative, and stomachic powder, exhibited in the cure of diarrhoa, pyrosis, and diseases arising from acidity of the bowels, inducing much pain.

PULVIS CRETÆ COMPOSITUS CUM OPIO. Compound powder of chalk with opium. Pulvis e bolo compositus cum opio. Species e scordio cum opio. "Take of compound powder of chalk, six ounces and a half. Hard opium, powdered, four scruples." Mix. The dose from one scruple to two. The above powder, with the addition of opium, in the proportion of one grain to

two scruples.

PULVIS IPECACUANHÆ COMPOSITUS. Compound powder of ipecacuanhæ. "Take of ipecacuanha root, powdered, hard punctum, a point.) Lachrymal points. Two opium, powdered, of each a drachm; sul- small orifices, one of which is conspicuphate of potash, powdered, an ounce." ous in each eyelid, at the extremity of the Mix. PULVIS OPIATUS. See Pulvis cornu cum

PULVIS SCAMMONIÆ COMPOSITUS. Compound powder of scammony. Pulvis comiti Warwicensis. " Take of scammony gum resin, hard extract of jalap, of each two ounces; ginger-root, half an ounce." Reduce them separately to a very fine pow-der, and then mix. From ten to fifteen grains or a scruple are exhibited as a stimulating cathartic.

PULVIS SCAMMONII CUM ALOE. A stimulating cathartic, in the dose of from ten to

fifteen grains.

PULVIS SCAMMONII CUM CALOMELANE. A vermifugal cathartic, in the dose of from

ten to fifteen grains.

PULVIS SENNÆ COMPOSITUS. Compound powder of senna. Pulvis diasenna. "Take of senna leaves, supertartrate of potash, of each two ounces; scammony gum resin, half an ounce; ginger root, two drachms." Reduce the scammony gum resin separately, the rest together, to a very fine powder; and then mix. The dose is from one scruple to one drachm. A saline stimulating cathartic.

PULVIS TRAGACANTHÆ COMPOSITUS. Compound powder of tragacanth. Species diatragacantha frigida. "Take of tragacanth, powdered, acacia gum, powdered, starch, of each an ounce and half; refined sugar, three ounces." Powder the starch and sugar together; then add the tragacanth and acacia gum, and mix the whole. Tragacanth is very difficultly reduced to powder. The dose is from ten grains to a drachm. A very useful demulcent powder, which may be given in coughs, diarrhœas, stranguary, &c.

Pumpion, common. See Cucurbita.

These changes arise more from indolence of the person who looks upon it like a and irritability, than from any absolute puppet.) The round opening in the mid- disease; many specific diseases, in healthy dle of the iris, in which we see ourselves in the eye of another.

PUPILLA. See Pupil

PUPILLARIS MEMBRANA. (From gonorrhæa, from the small-pox pustules, pupilla, the pupil.) Pupille velum. A fine the chicken pock, and from an healthy vascular membrane, which in the focus of ulcer, has the same appearance, and seems 5, 6, or 7 months has no pupil, grows to be made up of similar parts, consisting across the part where the pupil is after- of globules floating in a transparent fluid, like common pus; the specific properties of each of these poisons being superadded PURGATIVA. Purgentia. Cathartica. to those of pus. Matter from a cancer Catoretica. Catoteretica. may be considered as an exception; but Dejectoria. Alviduca. Purgative medi. a cancerous ulcer is never in a healthy

In indolent ulcers, whether the indolence arises from the nature of the parts, or the nature of the inflammation, the pus is made of globules and flaky particles, floating in a transparent fluid; and globules and flakes are in different proportions, according to the degree of indolence: this is particularly observable in scrophulous abscesses, preceded by a small degree of inflammation. That this flaky appearance is no part of true pus, is well illustrated by observing, that the proportion it bears to the globules is greatest where there is the least inflammation; and in those abscesses that sometimes occur, which have not been preceded by any inflammation at all, the contents are wholly made up of a curdy or flaky substance, of different degrees of consistence, which is not considered to be pus, from its not having the properties stated in the

The constitution and part must be in white colour; has a mawkish taste; and, changes in the general health are capable when cold, is inodorous; but, when warm, of producing an alteration in it, and even

This happens most readily in ulcers in

Pus differs from chyle in its globules,

being larger, not coagulating by exposure a slight elevation of the cuticle, and terto the air, nor by heat, which those of minating in a laminated scab chyle do.

The pancreatic juice contains globules, but they are much smaller than those of

Milk is composed of globules, nearly of the same size as those of pus, but much more numerous. Milk coagulates by runnet, which pus does not; and contains oil and sugar, which are not to be discovered

The cases in which pus is formed are, properly speaking, all reducible to one, which is, the state of parts consequent to inflammation. For, as far as we yet know, observes Mr. Home, pus has in no instance been met with unless preceded by inflammation; and although, in some cases a fluid has been formed independent of ed us, that in his time the green rind of preceding inflammation, it differs from pus in many of its properties.

formation of pus, it is necessary to take notice of the periods which are found, un- green and dried state; it has been greatly der different circumstances, to intervene recommended by writers on the continent, between a healthy or natural state of the as well as by those of our own country; parts, and the presence of that fluid after and is, without doubt, a very useful addi-

RACHIALGIA. (From gazis, the spine, and axque, pain.) A pain in the spine. It was formerly applied to several species of cholic which induced pain in the back.

RACIIITIS. (From gazis, the spine of the back; so called because it was supposed to originate in a fault of the spinal marrow.) Crytonosus The English disease. The rickets. A species of disease in the class cachexia, and order intumescentile of Cullen; known by a large head, prominent forehead, protruded sternum, flattened ribs, big belly, and emaciated limbs, with great debility. It is usually confined in its attack between the two periods of nine months and two years of age, seldom appearing sooner than the former, or shewing itself for the first time, after the latter period. The muscles become flaccid, the head enlarges, the carotids are distended, the limbs waste away, and their epiphyses increase in bulk. The bones and spine of the back are variously distorted; disinclination to muscular exertion follows; the abdomen swells and grows hard; the

R. on B. This letter is placed at the stools are frequent and loose; a slow fever spiration: atrophy is confirmed, and death ensues. Frequently it happens that nature restores the general health, and leaves the limbs distorted.

After death, the liver and the spleen have been found enlarged and scirrhous; the mesenteric glands indurated, and the lungs either charged with vomice, or adhering to the pleura; the bones soft, the brain flaccid, or oppressed with lymph, and the distended bowels loaded most frequently with slime, sometimes with worms.

It is remarkable, that in the kindred disease, which Hoffmann and Sauvage call the atrophy of infants, we have many of the same symptoms and the same appearances nearly after death. They who perish by this disease, says Hoffmann, have the mesenteric glands enlarged and scirrhous; the liver and spleen obstructed, and increased in size; the intestines are much inflated, and are loaded with black and fætid matters, and the muscles, more especially of the abdomen, waste away.

RANUNCULUS. (Dim. of rana, a frog; because it is found in fenny places, where frogs abour d.) The name of a genus of plants in the Linnzan system. Class, Poly-

andria. Order, Polygynia.

The great acrimony of most of the species of ranunculus is such, that, on being applied to the skin, they excite itching, redness, and inflammation, and even produce blisters, tumefaction, and ulceration of the part. On being chewed, they corrode the tongue; and, if taken into the stomach, bring on all the deleterious effects of an acrid poison. The corrosive plant. acrimony which this family of plants possesses, was not unknown to the ancients, ed crow foot. The roots and leaves of this as appears from the writings of Dioscori- plant, Ranunculus bulbosus of Linnaus:des; but its nature and extent had never culycibus retroflexis, pedunculis sulcatis, caule been investigated by experiments, before those instituted by C. Krapf, at Vienna, by which we learn, that the most virulent of fiery taste. Taken internally, they apthe Linnaan species of ranunculus, are the pear to be deleterious, even when so far bulbosus, sceleratus, acris, arvensis, thora, and illyricus.

The effects of these were tried, either upon himself or upon dogs, and shew that manifesting itself either in the roots, pressed juice, extract, decoction, and infusion of the plants, were also subjected to experiments. In addition to these specics mentioned by Krapf, we may also notice the R. Fammula, and especially the R. Alpestris, which according to Haller, is the most acrid of this genus. Mr. Curtis observes, that even pulling up the ranunculus acris, the common meadow spe- sus. cies, which possesses the active principle of this tribe, in a very considerable degree, foot. The leaves of this species of crowthroughout the whole herb, and carrying foot, Ranunculus sceleratus of Linnaus, it to some little distance, excited a considerable inflammation in the palm of the hand in which it was held. It is necessary to remark, that the acrimonious quality of and acrimonious ulceration. these plants is not of a fixed nature; for it

but where inflammation has been the cause, and the plant, on being thoroughly dried, we always find matter mixed with the becomes perfectly bland. Krapf attemptmost of the plants of this genus, depends RANUNCULOIDES. (From ranunculus, and much upon the situation in which they grow, and is greatly diminished in the cultivated plant.

RANUNCULUS ABORTIVUS, The systematic name of a species of ranunculus, which posesses acrid and vesicating pro-

perties.

RANUNCULUS ACRIS. The systematic name of the meadow crow-foot. See Ranunculus pratensis.

RANUNCULUS ALBUS. The plant which bears this name in the pharmacopæias is the Anemone nemerosa of Linnaus. The bruised leaves and flowers are said to cure tinea capitis applied to the part. The inhabitants of Kamschatka, it is believed, poison their arrows with the root of this

RANUNCULUS BULBOSUS. Bulbous rooterecto multifloro, foliis compositis, have no considerable smell, but a highly acrid and freed from the caustic matter by boiling in water, as to discover no ill quality to the palate. The effluvia, likewise, even when freely inspired, is said to occasion the acrimony of the different species is head aches, anxieties, vomitings, &c. The often confined to certain parts of the plant, leaves and roots, applied externally, inflame and ulcerate, or vesicate the parts, stalks, leaves, flowers, or buds; the ex- and are liable to affect also the adjacent parts to a considerable extent.

RANUNCULUS FICARIA. The systematic name of the pilewort. See Chelidonium minus.

RANUNCULUS FLAMMULA. The systematic name of the smaller water crow-foot, or spearwort. Its virtues and qualities are similar to those of the Ranunculus bulbo-

RANUNCULUS PALUSTRIS. Water croware so extremely acrid, that the beggars in Switzerland are said, by rubbing their legs with them, to produce a very fetid

RANUNCULUS PRATENSIS. Meadow crowmay be completely dissipated by heat; foot. Ranunculus acris of Linnaus. This, and some other species of ranunculus, cinally in the cure of calculous affections. have, for medical purposes, been chiefly employed externally as a vesicatory, and are said to have the advantage of a common blistering plaster, in producing a quicker effect, and never causing strangury; but, on the other hand, it has been observed, that the ranunculus is less certain in its operation, and that it sometimes occasions ulcers, which prove very troublesome and difficult to heal. Therefore their use seems to be applicable only to certain fixed pains, and such complaints as require a long continued topical stimulus or discharge from the part, in the way of an issue, which, in various cases, has been found to be a powerful remedy.

The systematus. The systematus.

matic name of the marsh crow-foot. See

Ranunculus palustris.

RAPA. Rapum. Rapus. Napus. Napus dulcis. The turnip. Brassica rapa of Lannæus. Turnips are accounted a salubrious food, demulcent, detergent, somewhat laxative and diuretic, but liable, in weak stomachs, to produce flatulencies, and prove difficult of digestion. The liquor pressed out of them, after boiling, is sometimes taken medicinally in coughs and disorders of the breast. The seeds are occasionally taken as diureties; they have no smell, but a mild acrid taste.

Rape. See Rapus.

RAPHANIA. (From raphanus, the radish, or sharlock; because the disease is said to be produced by eating the seeds of that plant.) Convulsio raphania, vel ab ustilagine. Eclampsia typhodes. Convulsio soloniensis. Necrosis ustilalaginea. Cripple disease. A genus of disease in the class nenroses, and order spasmi, of Cullen; characterised by a spasmodic contraction of the joints, with convulsive motions, and a most violent pain returning at various periods. It begins with cold chills and lassitude, pain in the head, anxiety about the pracordia. These symptoms are followed by spasmodic twichings in the ten-dons of the fingers and of the feet, dis-cernible to the eye, heat, fever, stupour, delirium, sense of suffocation, aphonia, and horrid convulsions of the limbs. After these, vomiting and diarrhoa come on, with a discharge of worms. About the cleventh or the twentieth day, copious sweats succeed, or purple exanthemata, or a portion of this infusion be taken with a tabes, or rigidity of all the joints.

oarresbar: from its quick growth.) The ed by itself to excite vomiting, or to ashorse-radish. A genus of plants in the sist the operation of other emetics. In-

der, Siliculosa.

RAPHANUS HORTENSIS Radicula. Rapharictics of this plant, Raphanus sativus of ing to the whole body; and thereby it Linnaus, are said to be employed medi- proves often useful in chronic rheumatism.

The juice, made into a syrup, is given to relieve hoarseness. Mixed with honey, or sugar, it is administered in pituitous asthma; and, as antiscorbutics, their efficacy is generally acknowledged.

RAPHANUS NIGER. See Raphanus horten-

RAPHANUS RUSTICANUS. Armoracia. Raphanus marinus. Raphanus sylvestris. Horse-radish. The plant which affords this root is the Cochlearia armoracia; foliis radicalibus lanceolatis crenatis, caulinis incisis of Linnaus, Horse-radish has long been received into the materia medica, is also well known at our tables. "It affects the organs both of taste and smell with a quick penetrating pungency; nevertheless it contains in certain vessels a sweet juice, which sometimes exudes in little drops upon the surface. Its pungent matter is of a very volatile kind, being totally dissipated in drying, and earried off in evaporation, or distillation by water, and rectified as the pungency exhales, the sweet matter of the root becomes more sensible, though this also is, in a great measure, dissipated or destroyed. It impregnates both water and spirit, by infusion, or by distillation, very richly with its active matters. In distillation with water, it yields a small quantity of essential oil, exceedingly penetrating and pungent."

Dr. Cullen has mentioned every thing necessary to be known respecting the medicinal virtues of horse-raddish, we shall therefore transcribe all that the ingenious professor has written on this subject. "The root of this only is employed; and it affords one of the most acrid substances of this order (Siliquose), and therefore proves a powerful sumulant, whether externally or internally employed. Externally, it readily inflames the skin, and proves a rubefacient that may be employed with advantage in palsy and rheumatism; and, if its application be long continued, it produces blisters. Taken internally, it may be so managed as to relieve hoarseness, by acting on the fauces. Received into the stomach, it stimulates this, and promotes digestion; and therefore is properly employed as a condiment with our animal food. If it be infused in water, and large draught of warm water, it readily RAPHANUS. (Paparos, waga to gablas, proves emelic, and may either be employ-Linnaan system. Class, Tetradynamia. Or- fused in water, and taken into the stomach, it proves stimulant to the nervous system, and is thereby useful in palsy; and, if em-The radish. The several va- ployed in large quantity, it proves heat-

whether arising from scurvy or other causes. Bergins has given us a particular method of exhibiting this root, which is, by cutting it down, without bruising, into small pieces; and these, if swallowed without chewing, may be taken down in large quantities, to that of a table-spoonful. And the author alleges, that, in this way, taken in the morning for a month together, this root has been extremely usefut in arthritic cases; which, however, I suppose to have been of the rheumatic kind. It would seem, in this manner employed, analogous to the use of unbruised mustard seed; it gives out in the stomach its subtle volatile parts, that stimulate considerably without inflaming. The matter of horse-radish, like the same matter of the other siliquose plants carried into the blood-vessels, passes readily into the kidneys, and proves a powerful dimetic, and is therefore useful in dropsy; and we need not say, that, in this monner, by promoting both urine and perspiration, it has been long known as one of the most powerful antiscorbutics."

RAPHANUS SATIVUS. The systematic name of the radish plant. See Ruphanus

nortensis.

RAPHANUS SYLVESTRIS. The poor man's pepper is sometimes so called. See Lepedium.

RAPHE SCROTI. ( $P\alpha\phi n$ , a suture.) The rough eminence which divides the scrotum, as it were, in two. It proceeds from the root of the penis inferiorly towards the perinaum.

RAPHE CEREBRI. The longitudinal eminence of the corpus callosum of the brain is so called, because it appears some-

what like a suture.

RAPISTRUM. (From rapa, the turnip, because its leaves resemble those of turnip.) Lampsana. Miagra. Charlock, or wild mustard.

RAPUM. (Ety. uncertain.) See Rapa. RAPUNCULUS. (Dim. of rapa, the turnip.)

The wild turnip.

RAPUNCULUS VIRGIANUS. The name given by Morrison to the blue cardinal flower. See *Lobelia*.

RAPUS. See Rapa.

RASH. Exanthema. A rash consists of red patches on the skin, variously figured; in general confluent, and diffused irregularly over the body, leaving interstices of a natural colour. Portions of the cuticle are often elevated in a rash, but the elevations are not acuminated. The cruption is usually accompanied with a general disorder of the constitution, and terminates in a few days by cuticular exfoliations.

RASPATORIUM. (From rado, to scrape.)

A surgeon's rasp.

Raspberry. See Rubus ideus.

RASURA. (From rado, to scrape.) 1. A rasure or scratch. 2. The raspings or shavings of any substance.

RATIFIA A liquor prepared by imparting to ardent spirits the flavour of various

kinds of fruits.

Ruttlesnake root. See Seneka.

RAUCEDO. (From raucus, hoarse.) Raucitas. Hoarseness. It is always symptomatic of some other disease.

RE-AGENT'S. Tests. Those substances which are used in chemistry to detect the substance for which they are used. In the application of tests there are two circumstances to be attended to, viz. To avoid deceitful appearances, and to have good tests.

The principal tests are the following:
1. Litmus. The purple of litmus is changed to red by every acid; so that this is the test generally made use of to detect excess of acid in any fluid. It may be used either by dipping into the water a paper stained with litmus, or by adding a drop of the tincture to the water to be examined, and comparing its hue with that of an equal quantity of the tincture in distilled water.

Litmus already reddened by an acid will have its purple restored by an alkali; and thus it may also be used as a test for alkalis, but it is much less active than other

direct alkaline tests.

2. Red cabbage has been found by Mr. Watt to furnish as delicate a test for acids as litmus, and to be still more sensible to alkalis. The natural colour of an infusion of this plant is blue, which is changed to red by acids, and to green by alkalis in

very minute quantities.

3. Brazil wood. When chips of this wood are infused in warm water they yield a red liquor, which readily turns blue by alkalis, either caustic or carbonated. It is also blued by the carbonated earths held in solution by carbonic acid, so that it is not an unequivocal test of alkalis till the earthy carbonats have been precipitated by boiling. Acids change to yellow the natural red of brazil wood, and restore the red when changed by alkalis.

4. Violets. The delicate blue of the common scented violet is readily changed to green by alkalis, and this affords a delicate test for these substances. Syrup of violets is generally used as it is at hand, being used in medicine. But a tincture of

the flower will answer as well,

\* 5. Turmeric. This is a very delicate test for alkalis, and on the whole perhaps is the best. The natural colour either in watery or spirituous infusion is yellow, which is changed to a brick or orange red by alkalis, caustic or carbonated, but not by carbonated earths, on which account it is preferable to Brazil wood.

produce the same change.

barb undergoes a similar change with tur-

meric and is equally delicate.

7. Sulphuric acid. concentrated sulphuric acid, added to water that contains carbonic acid, free or in combination, causes the latter to escape are the most delicate tests of muriatic with a pretty brisk effervescence, whereby acid, in any combination, producing the the presence of this gaseous acid may be detected.

They A muscle of the head. have no excretory duct, and their use is

It is supposed they answer one use in the fœtus, and another in the adult, but what these uses are is uncertain. Boerhaave supposed their use to consist in their furnishing lymph to dilute the blood returned after the secretion of the urine in the renal vein; but this is very improbable, since the vein of the right supra-lenal gland goes to the vena cava, and the blood carried back by the renal vein wants no dilution. It has also been said, that these glands not only pre-pare lymph, by which the blood is fitted for the nutrition of the delicate focus; but that in adults they serve to restore in themselves, to the blood of the vena cava, the irritable parts which it loses by the secretion of bile and urine. Some, again, have considered them as diverticula in the fætus, to divert the blood from the kid-(Dim. of rex, a king; so neys, and lessen the quantity of urine. RENNET. The gastric juice and contents of the stomach of calves. It is much employed in preparing cheese, and, in pharmacy, for making whey. To about a pound of milk, in a silver or earthen basin placed on hot ashes, add three or four grains of rennet, diluted with a little water: as it becomes cold the milk curdles, and the whey, or serous part, separates itself from the caseous part. When these parts appear perfectly distinct, pour the whole upon a strainer, through which the whey will pass, while the curds remain behind. This whey is always rendered somewhat whitish, by a very small and much divided Glandulæ renales. portion of the caseous part; but it may be Their figure is triangular; and ture with an ozier twig, and, having added

RENUENS. (From renuo, to nod the

REPELLENTIA. (From repello, to

Applications drive back.) Repellents. are sometimes so named which make diseases recede, as it were, from the surface

of the body.

REPULSION. All matter possesses a power which is in constant opposition to attraction. This agency, which is equally powerful and equally obvious, acts an important part in the phanomena of nature, and is called the power of repulsion.

That such a force exists which opposes the approach of bodies towards each other

is evident from numberless facts.

Newton has shown that when a convex lens is put upon a flat glass it remains at a distance of the one-hundred-and-thirtyseventh part of an inch, and a very considerable pressure is required to diminish this distance; nor does any force which can be applied bring them into actual mathematical contact; a force may indeed be applied sufficient to break the glasses into pieces, but it may be demonstrated that it does not diminish their distance much beyond the one-thousandth part of an inch. There is therefore a repulsive force which prevents the two glasses from touching each other.

Boscowich has shown that when an ivory billiard-ball sets another in motion by striking against it, an equal quantity of its own motion is lost, and the ball at rest begins to move while the other is still at a

distance.

There exists therefore a repulsion between bodies; this repulsion takes place while they are yet at a distance from each other; and it opposes their approach to-

wards each other.

The cause or the nature of this force is equally inscrutable with that of attraction, but its existence is undoubted; it increases as far as has been ascertained inversely as the square of the distance, consequently at the point of contact it is infinite.

The following experiments will serve to prove the energy of repulsion more fully.

Experiment .- When a glass tube is immersed in water the fluid is attracted by the glass, and drawn up into the tube; but, if we substitute mercury instead of water, we shall find a different effect. If a glass tube of any bore be immersed in this fluid it does not rise, but the surface of the mercury is considerably below the level of that which surrounds it.

In this case therefore a repulsion takes place between the glass and the mercury, which is even considerably greater than the attraction existing between the particles of the mercury, and hence the latter cannot rise in the tube, but is repelled, and

becomes depressed

Experiment - When we present the north pole of a magnet A, to the same pole of composition. another magnet B, suspended on a pivot, and at liberty to move, the magnet B vegetable kingdom, either by spontaneous

will recede as the other approaches; and by following it with A, at a proper distance, it may be made to turn round on its pivot with considerable velocity.

In this case there is evidently some agency which opposes the approach of the north poles of A and B, which acts as an antagonist, and causes the moveable magnet to retire before the other. There is therefore a repulsion between the two magnets, a repulsion which increases with the power of the magnets; which may be made so great that all the force of a strong man is insufficient to make the two north poles touch each other .- The same repulsion is equally obvious on electrical bodies, for instance.

Experiment -If two small cork balls be suspended from a body with silk threads so as to touch one another, and if we charge the body in the usual manner with electricity, the two cork balls separate from each other, and stand at a distance proportional to the quantity of electricity with which the body is charged; the balls of course

repel each other.

Experiment -If we rub over the surface of a sheet of paper the fine dust of lycopodium or puff ball, and then let water fall on it in small quantities, the water will instantly be repelled and form itself into distinct drops which do not touch the lycopodium, but roll over it with uncommon rapidity. That the drops do not touch the lycopodium, but are actually kept at a distance above it, is obvious from the copious reflection of white light.

Experiment -If the surface of water contained in a basin be covered over with lycopodium, a solid substance deposited at the bottom of the fluid may be taken out of it with the hand without wetting it. In this case the repulsion is so powerful as to defend the hand completely from the con-

tact of the fluid.

RES NATURALES. (From natura, nature.) The naturals. According to Boerhaave, these are life, the cause of life, and its effects. These, he says, remain in some degree, however disordered a person may be.

Reseda. (From resede to appease; so called from its virtue of allaying inflamma-

tion.) The herb wild rocket.

In some plants the resin is deposited, in have some, and frequently considerable a concrete state, in the interstices of the wood, or other parts of the plant.

Resons, when concrete, are brittle, and have generally a smooth and conchoidal fracture; their lustre is peculiar, they are more or less transparent, and of a colour which is usually some shade of yellow, or brown; they are of a greater specific gravity than water; they are often odorous and sapid, easily fusible, and, on cooling,

become solid.

RESINA ALBA. See Resina flava. RESINA ELASTICA. See Indian rubber.

RESINA FLAVA. Resina alba. Yel. low resin, what remains in the still after distilling oil of turpentine, by adding water to the common turpentine. It is of very extensive use in surgery as an active detergent, and forms the base of the unguentum resina fluva.

RESINA LUTEA NOVI BELGII. Botany-bay gum. All the information that has been hitherto collected respecting the history of the yellow gum is the follow-

The plant that produces it is low and small, with long grassy leaves; but the fructification of it shoots out in a singular manner from the centre of the leaves, on a single straight stem, to the height of twelve or fourteen feet. Of this stem, which is strong and light, like some of the reed class, the natives usually make their spears. The resin is generally dug up out of the soil under the tree, not collected from it, and may perhaps be that which Tasman calls, 'gum lac of the ground.'

Mr. Boles, surgeon of the Lady Penrhyn, gives a somewhat different account; and as this gentleman appears to have paid considerable attention to the subject, his account may certainly be relied upon. After describing the tree in precisely the same manner as above, he observes, that at the top of the trunk of the tree, long grassy leaves grow in great abundance. The gum is found under these leaves in considerable quantities; it commonly exudes in round tears, or drops, from the size of a large pea to that of a marble, and sometimes much larger. These are by the heat of the sun frequently so much soft- has indeed sometimes been said to purge, ened, that they fall on the ground, and in and at others to occasion sweating, but this soft state adhere to whatever they fall they are not constant effects, and when upon; hence the gum is frequently found they do occur, it generally depends on mixed with dirt, wood, the bark of the some accidental circumstance. It should tree, and various other substances: so that seem 10 possess, in a very extensive deone lump has been seen composed of many gree, the property of allaying morbid irrismall pure pieces of various sizes united tability, and of restoring tone, strength,

These juices contain a dance, that one man may collect thirty or lecting it: they dig round the tree, and break off pieces of the roots which always quantities of the gum in them. This gum appears nearly, but not entirely, the same as that which exudes from the trunk of the tree; the former is often mixed with a strong smelling resinous substance of a black nature, and is so interwoven in the wood itself, that it is with difficulty separated. The latter appears a pure unmixed resinous substance.

Several experiments have been made. principally with the view of determining what menstrum would dissolve the gum the most readily, and in the greatest quantity, from which it appears alcohol and

ether dissolve the most.

The diseases in which this resin is administered, are those of the primæ viæ, and princip. lly such as arise from spasm, a debility, a loss of tone, or a diminished action in the muscular fibres of the stomach and bowels, such as loss of appetite, sickness, vomiting, flatulency, heart-burn, pains in the stomach, &c. when they were really idiopathic complaints, and not dependent upon any disease in the stomach, or affections of other parts of the body communicated to the stomach. In debilities and relaxations of the bowels, and the symptoms from thence arising, such as purging and flatulency, it has been found of good effect. In certain cases of diar-rhæa, however, (and it seemed those in which an unusual degree of irritability prevailed,) it did not answer so well, unless given in small doses, and combined with opiates, when the patient seemed to gain greater advantage than when opiates only were had recourse to. In case of amenorrhæa, depending on (what most of those cases do depend upon) a sluggishness, a debility, and flaccidity of the system, this medicine, when assisted by proper exercise and diet, has, by removing the symptoms of dyspepsia, and by restoring the tone and action of the muscular fibres, been found very serviceable. This medicine does not, in the dose of about half a drachm, appear to possess any remarkably sensible operation. It neither vomits, purges, nor binds the belly, nor does it materially increase the secretion of urine or perspiration. It

RESOLVENTS. (Medicamenta Resolventia, from resolvo, to loosen.)

indurations, &c.

(Respiratio, RESPIRATION. from respiro, to take breath.) Of all the essential or remarkable than those occasioned by the influence of the air, which to the heart, and which the right ventricle a red vermillion colonr, frothy, lighter, and two degrees warmer; it is also more easily coagulable, and separates a smaller proportion of serum. All these differences, which are so easily perceptible, are dependent upon the modifications arising from having been in contact with the atmospheric air.

In man, and in all animals of warm blood that have an heart composed of two anricles and two ventricles, the blood which has been carried into all the organs by the arteries, and brought back by the veins to the heart, cannot be returned into the arteries without having first passed through the lungs, forming a medium of inspiration, the intercostal muscles not

pulmonary or smaller circulation.

Mayow has given the most accurate idea to a pair of bellows, in the insule of which was an empty bladder, the neck of which were separated: the air, in fact, does not enter the lungs but when the thorax dilates and enlarges by the separation of its parietes. To effect respiration, which may be defined the alternate entrance and egress of air in the lungs, the thorax must expand to receive the air, and contract to expel it. The dilatation is called inspiration, the contraction expiration; the latter mains in the retort after distilling the bal- is always shorter than the other, its causes are more mechanical, and the muscular

powers have less influence.

The thorax in its usual state dilates only This by depressing the daphragm. The curved term is applied by surgeons to such sub-stances as discuss inflammatory tumours. straight by contraction, causes it to destances as discuss inflammatory tumours. straight by contraction, causes it to de-RESOLUTION. (Resolutio, from re-scend towards the abdomen, and thus desolvo, to loosen.) A termination of in-flammatory affections in which the diseases anterior parieties of this cavity which sink disappear without any abscess, mortifica-tion, &c. being occasioned. The term is diaphragm is then relaxed and ascends, also applied to the dispersion of swellings, being pressed back by the abdominal viscora, on which the large muscles react. When we have occasion for the admission respire, to take breath.) Of all the of a great quantity of air into the chest, changes the blood suffers in passing through it not only enlarges in length by the deour various organs, there are none more scent of the diaphragm, but its capacity is likewise increased in every direction. The intercostal muscles then contract, and is alternately received into, and expelled approximate the ribs between which they from the lungs during the act of respira- are placed; yet the intercostal spaces betion. The blood which the veins return come larger, particularly at the anterior part; for whenever oblique lines tend to sends into the pulmonary artery, is blackish become perpendicular to a vertical line, and heavy; its temperature only 30 de- and to form right angles with it, the intergrees of Reaumur's thermometer: if suffer- cepted spaces augment in proportion as ed to remain still, it coagulates slowly, and the lines, having been more oblique, apseparates a great portion of scrum. That proach the horizontal direction; besides, as which the pulmonary veins bring back to the ribs present a double curvature in rethe left cavities of the heart, and which spect to their length, one on the front, the is conveyed into every part of the body by other on their sides, the convexity of the means of the arteries, is, on the contrary, of former is outwards, they separate from the axis of the chest, the cavity of which is enlarged transversely, while the latter curvature, agreeable to its edges, being augmented by a true rotatory motion, has its inferior edge pushed forwards. The thorax therefore increases both in its right and transverse diameter, each of which has been estimated to expand two lines; the extension of the vertical diameter dependent on the descent of the diaphragm is much more considerable.

When any cause whatever renders inspiration difficult, and prevents the diaphragm from descending towards the abdomen, or in any other manner impedes the motion which the blood must necessarily traverse only evidently act to induce a dilatation

of the thorax, but also several other These changes, compared with those the auxiliary muscles, as the scaleni subsca- blood has suffered in its passage through pulares, pectorales, serrati majores, latis- the lungs, manifestly indicate a reciprocal simi dorsi, in contracting raise the ribs, action of this liquid and the oxygen of the and increase the diameter of the thorax atmosphere. The dark venous blood, slow in several directions; the fixed point of of coagulation, and separating much se-these muscles should then be their move- rum, loaded with hydrogen and carbon, able part, because the cervical spine, the clavicle, scapola and humerus are fixed by other powers which it would be needless to enumerate. Inspiration is a state truly active, an effort of the contractile organs, which must cease when they fall into a state of relaxation. Expiration, which succeeds, is a passive motion in which few muscles co-operate, and chiefly depends on the re-action of the elastic parts constituting the structure of the parietes of the chest. It has been seen that the cartilages of the ribs experience a degree of rotation, carrying their upper edge backwards and downwards: when the cause that is productive of this action ceases to act, the parts return upon themselves, and carry back the sternum on the spine, towards which the ribs descend by their own gravity. The diaphragm is pushed nearer the thorax by the abdominal viscera, on which the large muscles of the abdomen react.

In every effort of expiration, as coughing and vomiting, the muscles react, not only in consequence of their own elasticity, but they still contract and approximate the spine, propelling the viscera towards the thorax. The musculus triangularis of the sternum, the subcostales, and the seratus minor inferior, may be ranked among the expiratores, but they are seldom employed, and form too slender and weak powers to contribute much to the contraction of When the chest enlarges, this cavity. the lungs dilate, following the parietes which expand, and each time the thorax dilates in an adult man, from thirty to forty cubic inches of atmospheric air en er into the lungs, and, when in a state of purity, composed of seventy-three parts of azot, twenty-seven parts of oxygen and onehundredth or two-hundredths of carbonic acid. After the atmospheric air has remained for some time in the pulmonary structure, it is expelled by the efforts of expiration, and its quantity is diminished to thirty eight inches. And, if examined, the composition is not the same: there are found certainly seventy-three hundredths of azot, but the oxygen, its vital and respirable part, has suffered great diminution, its proportion is only fourteen-hundredths; carbonic acid constitutes the remaining thirteen hundredths, and sometimes one or two parts of hydrogen gas are found. is likewise altered by the admixture of an aqueous vapour, which condenses in cold weather in passing out of the nostrils and mouth. This is known by the name of the humour of pulmonary exhalation.

possesses only thirty degrees of heat, gives off to the oxygen of the atmosphere its hydrogen and carbon, to constitute the carbonic acid, and pulmonary vapour; and, as oxygen cannot enter these new combinations without disengaging a portion of caloric, which rarefies it into gas, the blood seizes this heat, now liberated with so much greater facility as it proportionably loses its hydrogen and carbon, and, agreeable to the ingenious experi-ments of Crawford, its capacity for caloric augments in the relation of 10: 11: 5.

The blood in its passage through the lungs, is deprived of hydrogen and carbon, and, in becoming arterial, is loaded with oxygen and caloric, which are formed into oxyds of hydrogen and carbon; these, by a fresh addition of oxygen, which is derived from the atmospheric air in the lungs, form

water and carbonic acid.

Arterial blood becomes venous when any cause suspends or retards is course, as proved by the following experiment of J. Hunter. He tied the carotid of a dog in two places, at about four inches distance; the blood which came out of that portion of the artery between the ligatures, when opened several hours afterwards, was coagulated and dark like that of the veins.

The blood flowing in small veins very much resembles that of the arteries; and often in a copious bleeding the colour of the blood, at first very dark, becomes gradually paler, so that, towards the end of the operation, the blood which flows exhibits the qualities of that in the arteries. which is occasioned by rendering a more easy and direct passage of the blood from the arteries into the veins by emptying the venous system.

Richerand, in explaining the theory of respiration, thinks it probable that the oxvgen obsorbed in uniting with the hydrogen of every part of the body, produces the water that dilutes the venous blood, which is more fluid, and abounds more in serum than arterial blood; whilst this in uniting with carbon, forms an oxyd that gives this blood a dark colour, constituting one of its principal characteristics. The water in the lungs exhales, dissolved by the air, and forms pulmonary transpiration or exhalation; the oxyd of carbon, more completely burnt by a super-addition of oxygen, constitutes carbonic acid, which gives the air, passed by expiration, the property of precipitating lime-water.

By means of the absorption of oxygen by venous blood, we can explain how the phænomena of respiration continues in pipe, and completely fills it. On dissect-every part of the body, and give rise to ing the body of a recently drowned animal, heat uniformly spread throughout all our no particular fulness of the vessels within organs. In proportion as the blood loses its caloric, for which its affinity or capacity diminishes as it becomes venous, the parts which give off their hydrogen and carbon seize it. If the lungs were the only organs in which the matter of hear could be disengaged, the temperature of these viscera should be much higher than that of other parts, and experience proves that it is not sensibly augmented.

Rest harrow. See Ononis.

RESTA BOVIS. The rest harrow is so called because it hinders the plough; hence resta bovis. See Ononis.

RESUSCITATION. The restoring of persons, apparently dead, to life. Under this head, strictly speaking, is considered the restoring of those who faint, or have breathed noxious and irrespirable air; yet it is chiefly confined to the restoring of those who are apparently dead from being immersed in a fluid, or by hanging. Dr. Curry, of Guy's hospital, has written a very valuable treatise on this subject; and such is its importance, that we have thought proper to insert the following account:

"From considering," he observes, "that a drowned person is surrounded by water instead of air, and that in this situation he makes strong and repeated efforts to breathe, we should expect that the water would enter and completely fill the lungs. This opinion, indeed, was once very general, and it still continues to prevail among the common people. Experience, however, has shown, that unless the body lies so long in the water as to have its living principle entirely destroyed, the quantity of fluid present in the lungs is inconsiderable; and it would seem that some of this is the natural moisture of the part accumulated; for, upon drowning kittens, puppics, &c. in ink, or other coloured liquors, and afterwards examining the lungs, it is found that very little of the coloured liquor has gained admittance to them. To explain the reason why the lungs of drowned animals are so free from water, it is necessary to observe, that the muscles which form the opening into the wind-pipe are exquisitely sensible, and contract violently upon the least irritation, as we frequently experience when any part of the food or drink happens to touch them. In the efforts made by a drowning, person, or animal, to draw in air, the water rushes into the mouth and throat, and be stripped of any clothes it may have on, is applied to these muscles, which imme- and be immediately well dried. It should diately contract in such a manner as to then be wrapped in dry, warm blankets, contracted state continues as long as the the by-standers, and be removed as quickrelaxed and the water enters the wind- large apartment, in which a fire is ready,

the skull, nor any disease of the brain or its membranes, are visible. The lungs are also sound, and the branches of the windpipe generally contain more or less of a frothy matter, consisting chiefly of air, mixed with a small quantity of colourless fluid. The right cavity of the heart, and the trunks of the large internal veins which open into it, and also the trunk and larger branches of the artery which carries the blood from this cavity through the lungs, are all distended with dark coloured blood, approaching almost to blackness. left cavity of the heart, on the contrary, is nearly, or entirely empty, as are likewise the large veins of the lungs which supply it with blood, and the trunk and principal branches of the great artery which conveys the blood from hence to the various parts of the body. The external blood-vessels are empty; and the fleshy parts are as pale as if the animal had been bled to death. When a body has lain in the water for some time, other appearances will also be observable; such as, the skin livid, the eyes blood shot, and the countenance bloated and swoln; but these appearances, though certainly unfavourable, do not absolutely prove that life is irrecoverably gone. It is now known, that in the case of drowning, no injury is done to any of the parts essential to life; but that the right cavity of the heart, together with the veins and arteries leading to and from that cavity, are turgid with blood, whilst every other part is almost drained of this fluid The practice of holding up the bodies of drowned persous by the heels, or rolling them over a cask, is unnecessary; the lungs not being filled with any thing that can be evacuated in this way. Therefore such a practice is highly dangerous, as the violence attending it may readily borst some of those vessels which are already overcharged with blood, and thus convert what was only suspended animation, into absolute and permanent death. The operation of inflating the lungs is a perfectly safe, and much more effectual method of removing any frothy matter they may contain; and whilst it promotes the passage of the blood through them, also renders it capable of stimulating the left cavity of the heart, and exciting it to contraction. As soon as the body is taken out of the water, it should shut up the passage into the lungs. This or in the spare clothes taken from some of muscles retain the principle of life, upon ly as possible to the nearest house that can which the power of muscular contraction be got convenient for the purpose. The depends; when that is gone, they become fittest will be one that has a tolerably

ried in men's arms, or laid upon a door; mits of the operation of inflating the lungs or, in case the house be at a distance from 'he place, it a cart can be procured, let the body be placed in it, on one side, upon some straw, with the head and upper parts somewhat raised; and in this position a brisk motion will do no harm. Whatever be the mode of conveyance adopted, particular care should be taken that the head be neither suffered to hang backwards, nor to bend down with the chin upon the breast. When arrived at the house, lay body may be placed before the fire, or in the body on a mattress, or a double blanket, spread upon a low table, or upon a door supported by stools; the head and warm hands, or with cloths heated at the cliest being elevated by pillows. As the fire or by a warming-pan. The restoration air of a room is very soon rendered im- of heat should always be gradual, and the pure by a number of people breathing in it, for this reason as well as to avoid the confusion and embarrassment attending a crowd, no more persons should be admitted into the apartment where the body is exposed to it for some time, heat should be placed, than are necessary to assist immediapplied in a very low degree at first : and ately in the recovery; in general six will be if the weather be under the freezing point, found sufficient for this purpose, and these and the body when stripped, feels cold and should be the most active and intelligent nearly in the same condition with one that of the by-standers convenient to divide the assistents into two rub it well with snow, or wash it with sets; one set being employed in restoring cold water; the sudden application of heat the heat of the body, while the other in- in such cases, having been found very perstitutes an artificial breathing in the best nicious. In a short time, however, manner they are able. Every skilful per- warmth must be gradually applied. To son should be provided with a flexible tube assist in rousing the activity of the vital made of elastic gum, half a yard in length, principle, it has been customary to apply to introduce into the wind-pipe, and also various stimulating matters to different with a sum lar tube to which a syrynge can parts of the body. But as some of these be affixed, to be put into the esophagus applications are in themselves hurtful, Should these not be at hand, air should be and the others serviceable only according to thrown into the lungs in the best manner that can be suggested at the time. Should it will be proper to consider them particuit still be found that the air does not pass readily into the lungs, immediate recourse must be had to another and more effectual method for attaining that object. As this method, however, requires address, and also some knowledge of the parts about the throat, we would recommend that in proportion as it is deprived of heat, and when there is not a medical gentleman present, the mode already described be tried repeatedly before this be attempted. As a quantity of frothy matter occupying the drowned body, all stimulating applications branches of the wind-pipe and preventing the entrance of the air into the lungs, is generally the circumstance which renders this mode of inflation necessary, the mouth should be opened from time to time to remove this matter as it is discharged. has in some cases produced sores, While one set of the assistants are engaged which were very painful and difficult to in performing artificial respiration, the heal after recovery. Spirits of all kinds other should be employed in communicate evaporate fast, and thereby, instead ing heat to the body. The warm bath has of creating warmth, as they are expected been usually recommended for this purto do, carry off a great deal of heat from pose; but wrapping the body in blankets, the body. Spirit of hartshorn, or of sal pose; but wrapping the body in blankets, the body. Spirit of hartshorn, or of sal or woollen clothes, strongly wrung out of volatile, are liable to the same objection warm water, and renewing them as they grow cool, besides being a speedier and practicable method of imparting assistants. When there is reason to thirk

or can be made. The body may be car- heat, has this great advantage, that it adbeing carried on without interruption. Until a sufficient quantity of warm water can be got ready, other methods of restoring warmth may be employed; such as the application of dry, warm blankets round the bo y and limbs; bags of warm grains or sand. bladders or hottles of hot water, or hot bricks applied to the hands, feet, and under the arm-pits, the bottles and bricks being covered with flannel: or the the sunshine if strong at the time, and be gently rubbed by the assistants with their warmth applied ought never to be greater than can be comfortably borne by the assistants. If the weather happen to be cold, and especially if the body has been It will be found most is frozen, it will be necessary at first to the time and manner of their employment, larly. The application of all such matters in cases of apparent death, is founded upon the supposition that the skin still retains sensibility enough to be affected by them. It is well known, however, that even during life, the skin loses sensibility does not recover it again until the natural degree of warmth be restored. Previous to the restoration of heat, therefore, to a are useless, and so far as they interfere with the other measures, are also prejudicial. The practice of rubbing the body with salt or spirits is now justly condemned. The salt quickly frets the skin, and

sensibility, let an assistant moisten his flexible tube. The quantity of fluid thrown part: in this way evaporation is prevented, the addition of one or other of the and the full stimulant effect of the application obtained. A liniment composed using, however, only half the quantities of equal parts of spirit of hartshorn and mentioned there. As soon as the pulse or sallad oil, well shaken together, would beating of the heart can be felt, the inside appear to be sufficiently stimulating for of the nostrils may be occasionally touchthe purpose, and as it evaporates very ed with a feather dipt in spirit of hartsslowly, will admit of being rubbed on horn, or sharp mustard; it being found by without producing cold. The places to experience, that any irritation given to without producing cold. The places to experience, that any irritation given to which such remedies are usually applied, the nose, has considerable influence in are, the wrists, ankles, temples, and the exciting the action of the muscles concernparts opposite the stomach and heart, ed in respiration. When the natural The intestines, from their internal situation breathing commences, the flexible tube and peculiar constitution, retain their irribation that may be necessary, body, and, accordingly, various means performed by blowns into the pasts. and peculiar constitution, retain their irritability longer than the other parts of the body, and, accordingly, various means have been proposed for increasing the action of their fibres, in order to restore activity of the whole system. Tobaccosmoke, injected by way of clyster, is what has been generally employed with this view, and the fumigator, or instrument for administering it, makes a part of the apparatus which is at present distributed by the different societies established for the recovery of drowned persons. Of late, however, the use of tobacco-smoke has been objected to, and upon very strong grounds; for when we consider that the same remedy is successfully employed with the very opposite intention, namely, that of lessening the power of contraction in the muscles, and occasioning the greatset relaxation consistent with life, it must be acknowledged to be a very doubtful, if not dangerous remedy, where the powers of life are already nearly exhausted. Instead of tobacco-smoke then, we would recommend a clyster, consisting of a pint or more of water, moderately warmed, withthe addition of one or two table-spoonful of essence of peppermint: in defect of one or other of these, half a gill or more, of rum, brandy, or gin may be added, or the warm water given alone. or more, of rum, brandy, or gin may be yet known, and capable of exciting con-added, or the warm water given alone, traction in the heart and other muscles of This step however, need not be taken, the body, after every other stimulus had until artificial respiration has been begun; ceased to produce the least effect. Modefor it will answer but little purpose to sti-rate shocks are found to answer best, and mulate the heart through the medium of these should, at intervals, bepassed through the intestines, unless we, at the same time, the chest in different directions, in order, supply the left cavity with blood fitted to if possible, to rouse the heart to act act upon it; which we cannot do without Shocks may likewise be sent through the first removing the collapsed state of the limbs, and along the spine; but we are lungs, and promoting the passage of the doubtful how far it is safe or useful to pass blood through them by a regular inflation, them through the brain, as some have re-As the stomach is a highly sensible part, commended. The body may be conveand intimately connected with the heart niently insulated, by placing it on a door, and brain, the introductoin of some mode- supported by a number of quart bottles, rately warm and stimulating liquor into whose sides are previously wiped with a it, seems well calculated to rouse the dor- towel to remove any moisture they may mant powers of life. on different animals, it is found that the pain in the breast or side, increased on when they are fully distended with air; consequently, that if the lungs of a drowned person are inflated, and kept in the expanded state whilst the electric shock is passed through the chest, the blood accumulated in the right cavity of the heart and its vessels, will move forward without any resistance, should the heart be brought to contract upon it. As soon as the shock air they contain, and filled again with fresh air; then pass another shock, and repeat this until the heart is brought into action, or until it appear that all farther attempts are useless. In order more certainly to pass the shock through the heart, place the knob of one discharging rod above the collar-bone of the right side, and the knob of the other above the short ribs of the left: the position of the discharging rods, however, may be changed occasionally, so as to vary the direction of the shock. Two thick brass wires, each about eighteen inches long, passed through the two glass tubes, or wooden cases, well varnished, and having at one end a knob, and at the other a ring to fasten the brass chain to, form very convenient discharging rods; and by means of them, the shock may be administered without the risk of enlarged, and prominent. On dissection, its being communicated to the assistants, the blood-vessels of the brain are found or carried off by the skin being wet, considerably distended; but in general, When the patient is so far recovered as to no further marks of disease appear within be able to swallow, he should be put into the skull. The lungs are found generally a warm bed, with his head and shoulders quite collapsed, and free from frothy somewhat raised by means of pillows. matter. The heart and the large blood-Plenty of warm wine-whey, ale-posset, or vessels adjoining to it, exhibit the same other light and moderately nourishing appearances as in the bodies of drowned drink, should now be given, and gentle persons. From the great accumulation of sweating promoted, by wrapping the feet and legs in flannels well wrung out of hot water. If the stomach and bowels feel distended and uneasy, a clyster, consisting of a pint of warm water, with a table spoonful of common salt, or an ounce or more of Glauber's or Epsom salt, dissolved in it, may be administered. The general practice, in this case, is to give an emetic; but considering that the powers of the machine are still very weak, the agitation of vomiting is certainly hazardous. The patient should on no account be left alone, until the senses are perfectly restored, and he be able to assist himself; several persons having relapsed and been lost, from want of proper attention to them, after the vital functions were, to all appearance, completely established. Either from the distention which the arteries of the lungs have suffered, or from the sudden change from great coldness to considerable warmth, it now and then happens, that the patient is attacked, soon after recovery, with inflammation of some of the parts within the chest. This occurrence is pointed out by

blood passes through the lungs most readily inspiration, and accompanied with frequent, and full or hard pulse, and sometimes with cough. Here the taking away some blood from the arm, or the application of cupping-glasses, leeches, or a blister, over the seat of the pain, will be very proper; but the necessity for these measures, as well as the time for putting them in practice, should be left to the judgment and discretion of a medical person. Dull pain in is given, let the lungs be emptied of the the head, lasting sometimes for two or three days, is by no means an unfrequent complaint in those who are recovered from this and from the other states of suspended animation; and here also a moderate bleeding from the neck, either with the lancet or with cupping-glasses, may prove serviceable.

> In hanging the external veins of the neck are compressed by the cord, and the return of the blood from the head thereby impeded, from the moment that suspension takes place; but as the heart continues to act for a few seconds after the wind-pipe is closed, the blood which is sent to the head during this interval, is necessarily accumulated there. Hence it is, that in hanged persons the face is greatly swoln, and of a dark red or purple colour: the eyes are commonly suffused with blood, blood in the vessels of the head, many have been of opinion, that hanging kills chiefly by inducing apoplexy; but the following experiment made at Edinburgh several years ago, by an eminent medical professor there, clearly proves, that in hanging, as well as in drowning, the exclusion of air from the lungs is the immediate cause of A dog was suspended by the death. neck with a cord, an opening having been previously made in the wind-pipe, below that place where the cord was applied, so as to admit air into the lungs. In this state he was allowed to hang for three quarters of an hour, during which time the circulation and breathing went on-He was then cut down, without appearing to have suffered much from the experiment. The cord was now shifted below the opening into the wind-pipe, so as to prevent the ingress of air to the lungs; and the animal being again suspended, he was completely dead in a few minutes. Upon the whole, then, it appears, that the same measures recommended for drowned persons, are also necessary here:

wish this addition, that opening the jugular are inserted into that part of the back of veins, or applying cupping-glasses to the the ear which is opposite to the septum neck, will tend considerably to facilitate which divides the concha and scapha. the restoration of life, by lessening the Their use is to draw the ear backwards, the restoration of life, by lessening the quantity of blood contained in the vessels of the head, and thereby taking off the pressure from the brain. Except in persons who are very full of blood, the quantity taken away need seldom exceed an ordinary tea cupful, which will in general be sufficient to unload the vessels of the head, without weakening the powers of lifc.

RETE. A net. A congeries of vessels, or any animal substance resembling a net. RETE MALPHIGIT. A fine net-work of the extremities of the pulmonary arteries.

RETE MIRABILE. A net-work of bloodvessels in the basis of the brain of quad-

rupeds.

RETE MUCOSUM. Corpus reticulare. Corpus mucosum. Mucus Malphigii. mucous substance, deposited, in a net-like form, between the epidermis and cutis, which covers the sensible cutaneous papilla, connects the epidermis with the cutis, and gives the colour to the body: in Europeans it is of a white colour, in Ethiopians black. See Skin.

RETICULAR. (Rationlaris, from rete,

a net.) Interwoven like a net.

RETIFORM. (Retiformis, from rete, a net, and forma, resemblance.) Net-like.

RETINA. (From rete, a net.) phiblestroides. The third or innermost membrane of the eye, expanded round the choroid coat, to the ciliary ligament. It is the true organ of vision, and is formed by an expansion of the pulp of the optic nerve.

RETINACULUM. (From retineo, to prop or restrain.) An instrument for keeping

the bowels in their place.
RETORT. (Retorta, from retorqueo, to bend back again; probably so called because its neck was curved and bent back again.) A chemical vessel employed for many distillations, and most frequently for those which require a degree of heat superior to that of boiling water. They differ in form and materials: when pierced with a little hole in their roof, they are called tubulated retorts. They are made of common glass, stone ware, and iron

RHABARBARUM. (From Rha, and barbarus, wild; so called because it was brought from the banks of the Rha, now called the Wolgar, in Russia.) Lapathum Rheum. Rhaum. Barbaria. orientale. Lapathum chinense. rum verum. Rhabarbarum tartaricum. Rhubarb. It was not until the year 1732 that naturalists became acquainted with any plant which seemed to afford the Rhabarbarum officinale, when some plants received from Russia by Jussieu at Paris, and Rhaud at Chelsea, were said to supply this important desideratum, and as such were adopted by Linnaus, in his first edition of the species Plantarum, under the name of Rheum Rhabarbarum. This, however, was not generally received as the genuine rhubarb plant; and with a view to ascertain this matter more completely, Kaw Boerhaave procured from a Tartarian rhubarb merchant the seeds of those plants whose roots he annually sold, and which were admitted at Petersburgh to be the true rhubarb. These seeds were soon propagated, and were discovered by Gorter to produce two distinct species, viz. the R. Rhabarbarum of Linnæus, or as it has since been called, the R. Undulatum, and another species, a specimen of which was presented to Linnæus, who declared it to be a new one, and was first mentioned in the second edition of the species Plantarum, in 1762, by the name of R Palmatum. Previous to this time De Gorter had repeatedly sent its seeds to Linnæus, but the young plants which they produced constantly perished; at length he obtained the fresh root, which succceded very well at Upsall, and afterwards enabled the younger Linnaus to describe this plant, ann. 1767. But two years antecedent to this, Dr. Hope's account of the Rheum palmatum, as it grew in the botanic garden near Edinburg, had been read before the Royal Society at London; and Two of the great estimation in which this plant

possessed of the plant which produces the moderately purgative. The qualities of true rhubarb, and may reasonably enter- this root, says Dr. Cullen, are that of a tain the agreeable expectation of its proving a very important acquisition to Britain."

RHA

But from the relation we have given, it appears that both the seeds of the R. Palmatum, and the R. Undulatum, were transmitted to Petersburgh, as those of the true rhubarb; we are therefore to conclude, that the former species has an equal claim to this importance with the latter; and from further inquiries made in Russia, there is the best authority for believing that the R. Compactum also affords this very useful drug. The seeds of the R. Palmatum were first introduced into Britain in 1762, by Dr. Hounsy (who sent them from Russia,) and were supposed to be a part of that already mentioned; and since their prosperous cultivation by the late professor of botany at Edinburgh, the propagation of this plant has been gradually extended to most of our English gardens, and with a degree of success which promises in time to supersede the importation of the foreign root. Two sorts of rhubarb roots are usually imported into this country for medical use, viz. the Chinese, and the Tartary rhubarb; the first is in oblong pieces, flattish on one side, and convex on the other; compact, h rd, heavy, internally of a dull red colour, variegated with yellow and white, and when recently powdered, appears yellow, but on being kept becomes gra-dually redder. The second is the most valuable, and is brought to us in roundish pieces, with a large hole through the middle of each; it is more soft and friable than the former sort, and exhibits, when broken, many streaks of a bright red colour. "The marks of the goodness of rhubarb are, the liveliness of its colour when cut; its being firm and solid, but not flinty or hard; its being easily pulverable, and appearing when powdered of a fine bright yellow colour; its imparting to the spittle when chewed a deep saffron tinge, and not proving slimy or mucilagi-nous in the mouth; its taste is subacrid, bitterish, and somewhat styptic; the smell lightly aromatic."

The purgative qualities of rhubarb are extracted more perfectly by water than by rectified spirit: the root remaining after ponticum. the action of water is almost if not wholly inactive; whereas after repeated digestion in spirit, it proves still very considerably purgative. The virtue of a watery infusion, on being inspissated by a gentle heat is so much diminished, that a drachm of the extract is said to have scarcely any greater effect than a scruple of the root in the Rumex patientia of Linnxus, and, acoustance. The spirituous tincture loses cording to Professor Murray, from the

gentle purgative, and so gentle that it is often inconvenient on account of the bulk of the dose required, which in adults must be from 3ss to 3j. When given in a large dose it will occasion some griping, as other purgatives do; but it is hardly ever heating to the system, or shows the other effects of the more drastic purgatives. The purgative quality is accompanied with a bitterness, which is often useful in restoring the tone of the stomach when it has been lost; and, for the most part, its bitterness makes it sit better on the stomach than many other purgatives do. Its operation joins well with neutral laxatives; and both together operate in a lesser dose than either of them would singly. Some degree of stypticity is always evident in this medicine; and as this quality acts when that of the purgative has ceased, so, in cases of diarrhæa, when any evacuation is proper, rhubarb has been considered as the most proper remedy to be employed. It must, however, be remarked here, that in many cases of diarrhoa, no further evacuation than what is occasioned by the disease, is necessary or proper. The use of rhubarb, in substance, for keeping the belly regular, for which it is frequently employed, is by no means proper, as the adstringent quality is ready to undo what the purgative has done; but it is found that the purpose mentioned may be obtained by it, if the rhubarb is chewed in the mouth, and no more is swallowed than what the saliva has dissolved. And it must be remarked, that in this way employed it is very useful to dyspeptic persons. Analogous to this, is the use of rhubarb in solution, in which it appears to me, that the adstringent quality is not so largely extracted as to operate so powerfully as when the rhubarb was employed in substance."

The officinal preparations of this drug are, a watery and a vinous infusion, a simple and a compound tincture. It is also an ingredient in different compositions; as, the elixir ex aloe et rheo, pilulæ stomachica, and some others.

Rhapontic, rhubarb. See cum.

RHAPONTICUM. (The Rha of Pontus, i. e. the Rha, in Russia, a river on whose banks it grew.) Rhabarbarum dioscoridis. Rhabarbarum antiquorum. The root of this plant, Rheum rhaponticum of Linnæus, appears to have been the true rhubarb of rheumatici et arthritici of Hoffman. Myothe ancients. By some it is confounded with the modern rhubarb, though consi- its being formerly used in the same sense derably different from that root in appear- as rheuma; but, in the present day, the ance, as well as in quality. The rhapontic meaning of this word is applied to a genus

more adstringent than rhubarb, but comes loose spongy texture; is more adstringent than rlinbarb, and less purgative; in this RUABARBARUM SIBIRICUM. The plant last intention, two or three drachms are required for a dose.

RHAPONTICCM VULGARE OFFICINARUM. root of this plan Centaurea centaureum of Linnaus, was formerly used as an aperient and corroborant in alvine fluxes. It is now totally discarded from the Materia Medica

of this country.

RHATANIA. This substance has been long known to the manufacturers of port wine; it is the production of Peru, and is probably the root of the cinchona cordifolia. It is described as externally resembring the root of the rubia tinctorum, to the taste, being aromatic, bitter and veryadstringent; its infusion or decoction turns black with sulphate of iron and precipitates tannin. The principal virtues appear to reside in the cortical part of the root which is thick and resinous. An opinion prevails that the substance sold in the shops under the name of foreign extract of bark is made from the rhatania.

It is well known that the medical virtues of this root are powerfully tonic. In debility of the digestive organs, in chronic rheumatism, fluor albus, and in intermittent fevers it has been employ d with good effect. While given in doses similar to cinchona, it has the advantage of being only one third

the price of that substance.

Rheu- attacked with it, is ever afterwards more matism is distinguished into acute and or less liable to returns of it; and an inchronic. The acute is preceded by shiver- curable anchylosis is sometimes formed, in ing, heat, thirst, and frequent pulse; after consequence of very frequent relapses, which the pain commences, and soon fixes Neither is the acute rheumatism frequently on the joints. The chronic rheumatism is accompanied with much danger; but, in a distinguished by pain in the joints, without few instances, the patient has been depyrexia, and is divided into three species; stroyed by general inflammation, and, now lumbago, affecting the loins; and ischias, and then, by a metastasis to some vital or schiatica, affecting the hip, and arthro-part, such as the head and lungs. Acute dynia, or pains in the joints. The acute rheumatism, although accompanied with a species mostly terminate in one of these considerable degree of inflammation in

Rheumatism may arise at all times of the year, when there are frequent vicissitudes of the weather, from heat to cold, but the spring and autumn are the seasons in which it is most prevalent; and it attacks persons of all ages; but very young people are less subject to it than adults.

Obstructed perspiration, occasioned either by wearing wet clothes, laying in damp linen, or damp rooms, or by being exposed to cool air when the body has been much heated by exercise, is the cause which usually produces rheumatism. Those who are much afflicted with this complaint, are very apt to be sensible of the approach of wet weather, by finding wandering pains about them at that period.

Acute rheumatism usually comes on with lassitude and rigors, succeeded by heat, thirst, anxiety, restlessness, and a hard pulse; soon after which, excruciating pains are felt in different parts of the body, but more particularly in the joints of the shoulder, wrist, knees, and ankles, or perhaps in the hip; and these keep shifting from one joint to another, leaving a redness and swelling in every part they have occupied, as likewise a great tendency to Towards evening there is the touch. usually an exacerbation, or increase of fever; and, during the night, the pains be- of the root resides. Poultices in which come more severe, and shift from one joint to another.

Early in the course of the disease, some degree of sweating usually occurs; but it is seldom so copious as either to remove the pains or to prove critical. In the beginning, the urine is without any sediment; but as the disease advances in its progress, and the fever admits of considerable remissions, a lateritious sediment is deposited; but this by no means proves critical.

Chronic rheumatism is attended with pains in the head, shoulders, knees, and other large joints, which at times are confined to one particular part, and at others rose, and foregon, a tree; so called beshift from one joint to another, without cause its flowers resemble the rose.) 1.

No danger is attendant on chronic rheu. Rheumatism terminates in matism; but a person having been once particular parts, has seldom been known to terminate in suppuration; but a serous or gelatinous effusion takes place.

Rheumatism seldom proving fatal, very few opportunities have offered for dissections of the disease. In the few which have occurred, the same appearances have been observed in inflammatory fever, as effusion within the cranium, and now and then affections of some of the viscera.

RHIBESIA. (From ribes, a currant.) See Ribes nigrum, Ribes rubrum, and Fruits, summer.

RHINÆUS. (Rhinæus, sc. musculus; from piv, the nose.) See Compressor naris. RHINENCHYTES. (From giv, the nose, and εγχυω, to pour in.) A syringe for the

RHINOPHONIA. (From gir, the nose, and owen, the voice.) A nasal voice.

RHIZAGRA. (From eiga, the root, and ayeeva, to seize.) An instrument for taking out the roots or stumps of teeth.

RHODIA. (From godov, a rose; so called because its root smells like the damask rose.) The radix rhodiz of some pharmacopæias is the produce of the Rhodiola rosea of Linnæus, called rose-wort. When dry, it has a very pleasant smell, resembling that of the damask rose. In this odorous matter the medical virtue this root enters as a chief ingredient are said to allay violent pains of the head

Rhodium Lignum. (From godov, a rose; a wood which smells like roses.) Rhodium, or rose-wood. The wood or root of a tree supposed to be the Genista canariensis of Linnæus. It is brought from the Canary islands. An essential oil is obtained from it, which is used principally as a perfume, but passesses cordial and corroborant virtues. It is also an ingredient in the composition of powders for the destruction of rats.

RHODODENDRON. (From podov, a The name of a genus of plants in the Cervici dorso scapulaire of Dumas.

oleander. rhododendron. Siberia, affecting mountainous situations, and flowering in June and July.

Haller. Little attention, however, was paid to it, till the year 1779, when it was strongly recommended by Koelpin as an cflicacious medicine, not only in rhcumatism and gont, but even in venereal cases; and it is now very generally employed in chronic rheumatisms, in various parts of Europe. The leaves, which are the part directed for medicinal use, have a bitterish subadstringent taste. Taken in a large dose, they prove a narcotic poison; and, in moderate doses, they are said to occasion heat, thirst, a degree of dehrium, and a peculiar sensation of the parts affected.

As a powerful and active medicine, this shrub, says Dr. Woodville, may probably be found an addition to the materia medica. Dr. Home, who tried it insuccessfully in some cases of acute rhoumatism, says, "It appears to be one of the most powerful sedatives which we have, as, in most of the trials, it made the pulse remarkably slow, and in one patient reduced it to thirty-eight beats. And in other cases, in which the rhododendron has been used at Edinburgh, it has been productive of good effects, and accordingly it is now introduced into the Edinburgh Pharmacopæia." The manner of using this plant by the Siberians, was by putting two drachms of the dried leaves in an carthen pot, with about ten ounces of boiling water, keeping it near a boiling heat for a night; and this they took in the morning, and by repeating it three or four times, generally effected a

Raus Habicans. A poisonous plant, Rhus vernix of Linnaus, the efficacy of which Dr. Fresnoi has endeavoured to prove, in the disease called paralysis, and herpetic affections. He, in order that others should not suffer by his experiments, began by taking an infusion of one of the three folioli, of which each leaf of this plant consists; and as this dose produced no sensible effect, he increased the number to twelve. His urine and perspiration were increased in quantity, and he had some pains in his belly. He relates seven cases, in which he thinks he can remove all doubt of the efficacy of this infusion, in herpetic affections. From these the following are selected:

"A country woman," says Dr. Fresnoi, "came to me in the month of July, 1780. to consult me about the herpes farinosa, with which her face had been covered for more than a year. She was ordered to make an infusion of this plant; and, in six weeks, was entirely free from the disease."

He likewise relates five cases of paralysis, which were cured by the use of this

The leaves of this plant are to be cut of Douglas, Winslow, and Cowper; and on account of its poisonous qualities." The

Paulus Ægineta, and Pliny. The ricinus was first cultivated in England, in the time of Turner, and is now annually reared in many gardens in the neighbourhood of London; and in that of Dr. Saunders, at Highbury, the plant grew to a state of great An oil extracted from the perfection. seeds of this plant, and known by the name of oleum ricini, palma christi, or castor oil, is the drug to which the pharmacopæias refer, and which has lately come into frequent use, as a quick but gentle purgative.

The London College directs this oil to be expressed from the seeds in the same way as that of the oil of almonds, and without the assistance of heat, by which the oil would seem to be obtained in the purest state. However, we have some reason to believe that this method is seldom practised, and that the oil usually employed here is imported from the West Indies, where it is commonly prepared in the following manner:-" The seeds being freed from the husks. or pods, which are gathered upon their turning brown, and when beginning to burst open, are first bruised in a mortar, afterwards tied up in a linen bag, and then thrown into a large pot, with a sufficient quantity of water (about eight gallons to one gallon of the seeds,) and boiled till the oil is risen to the surface, when it is carefully skimmed off, strained, and kept for use. Thus prepared, the oil is entirely free from acrimony, and will stay upon the stomach when it rejects all other medicines." Mr. Long remarks, that the oil intended for medicinal use, is more frequently cold drawn, or extracted from the bruised seeds by means of a handpress. But this is thought more acrimonious than that prepared by coction. Browne is also of this opinion, and prefers the oil prepared by coction to that by expression; he attributes its greater mildness to the action of the fire, observing, that the expressed oil, as well as the mixed juices small fissure. of the seeds, are far more active and violent in their operation.

Dr. Cullen observes, that "this oil, when the stomach can be reconciled to it, is one of the most agreeable purgatives we can employ. It has this partic lar advantage, that it operates sooner after its exhibition than any other purgative I know of, as it commonly operates in two or three hours. It seldom gives any griping, and its operation is generally moderate, to one, two, or three stools only. It is particularly suited to cases of costiveness, and even to cases of spasmodic cholic.

In the West Indies, it is found to be one of the most certain remedies in the dry belly-ache, or colica pictonum. It is seldom found heating or irritating to the rectum; and therefore is sufficiently well suited to hæmorrhoidal persons.

The only inconvenience attending the use of this medicine is, that as an oil it is nauseous to some persons; and that, when the dose is large, it occasions sickness at the stomach for some time after it is taken. To obviate these inconveniences, several means have been tried; and it is found that the most effectual means is the addition of a little ardent spirit. In the West Indies, they employ rum; but that I might not withdraw any part of the purgative, I employ the Tinct. sennæ comp. This added, in the proportion of one to three parts of the oil, and very intimately mixed, by being shaken together in a phial, both makes the oil less nauseous to the taste, and makes it sit more easy on the stomach. The common dose of this oil is a tablespoonful, or half an ounce; but many persons require a double quantity.

RICINUS COMMUNIS. The systematic name of the plant which affords the castor-See Ricinus.

RICINUS MAJOR. Ricinoides. Pineus purgans. Pinhones indici. Faba cathartica. Nux cathartica americana. Nux barbaden. An oblong black seed, the produce of the Jairopha curcus; foliis cordatis angulatis of Lineaus. It affords a quantity of oil, which is given, in many places, as the castor-oil is in this country, to which it is very nearly allied. The seeds of the Jatropha multifida are of an oval and triangular shape, of a pale brown colour, are called purging-nuts, and give out a similar oil.

The pharmacopæias direct a stringent qualities, which are most consisyrup to be prepared from the petals of derable before the petals expand; and this rose. Rosa centifolia of Linnaus:— therefore in this state they are chosen for germinibus ovatis pedunculisque hispidis, medicinal use, and ordered by the pharcaule hispido aculeato, petiolis inermibus; macopaias in different preparations, as which is found to be a pleasant and useful those of a conserve, or confection, a honey, laxative for children, or to obviate cos ive- an infusion, and a syrup. The infusion of ness in adults. Most of the roses, though roses is a grateful cooling subadstringent, much cultivated in our gardens, are far from being distinctly characterised. Those morrhagic complaints; its efficacy, howdenominated varieties are extremely nu- ever, depends chiefly on the acid merous, and often permanently uniform; and the specific differences as hitherto pointed out, are in many respects so adequate to the purpose of satisfactory discrimination, that it becomes a difficult matter to distinguish which are species and which are varieties only. The London College, following Gerard and Parkinson, has still retained the name rosa damascena; but the damask rose is another species, widely different from the contifolia, as appears from the description given of it by Du Roi and Miller.

The petals are directed for medicinal people, is extremely agreeable; and therefore this and most of the other roses are ROCKAMBOLE. The Allium scorodophra- much used as nosegays. We may remark, sum of Linnaus. The root is used for however, that, in some instances, they have, under certain circumstances, produced alarming symptoms. The petals "impart their odorous matter to watery liquors, both by infusion and distillation. Six pounds of fresh roses impregnate, by distillation, a gallon, or more, of water, strongly with their fine flavour. On distilling large quantities, there separates from the watery fluid a small portion of a fragrant butyraceous oil, which liquifies by heat, and appears yellow, but concretes in the cold into a white mass. An hundred pounds of the flowers, according to the experiments of Tachenius and Hoffman, afforded scarcely half an ounce of oil." The smell of the oil exactly resembles that of roses, and is therefore much used as a perfume. It possesses very little pungency, and has been highly recommended for its flowers also contain a bitterish substance, which is extracted by water along with the odorous principle, and remains entire in the decoction after the latter has been separated by distillation, or evaporation.

This fixed sapid mater of the petals manifests a purgative quality; and it is on this account that the flowers are received

They prove most unfavourable to such as are of a plethoric or scrophulous habit. Like the small-pox, they never affect perappears to be of a specific nature. The eruption is usually preceded by a general uneasiness, chilliness and shivering, pain in the head, in grown persons; but in children, a heaviness and soreness in the throat, in most fevers; but the chief characteristic symptoms are, a heaviness about the eyes, with swelling, inflammation, and a defluxion of sharp tears, and great acuteness of sensation, so that they cannot bear the light without pain, together with a discharge of serous humour from the nostrils, which produces sneezing. The heat, and other febrile symptoms, increase very rapidly; to which succeeds a frequent and dry cough, a stuffing, great oppression, and oftentimes retching to vomit, with violent pains in the loins, and sometimes a looseness; at other times there is great sweating, the tongue foul and white, the thirst regular small pox. The eruptions appear tal. Dropsy has also been known as a conabout the fourth or fifth day, and some- sequence of measles. times about the end of the third. On the ninth or eleventh day, no trace of redness is to be found, but the skin assumes its wonted appearance; yet, without there have been some considerable evacuations either by the skin, or by vomiting, the patient will recover strength, but the cough will continue, the fever return with new violence, and bring on great distress

and danger

the limbs, subsultus tendinum, delirium, or what more frequently happens, coma This last symptom so fresupervene. quently attends the cruptive fever of measles, that by some practitioners it is regarded as one of its diagnostics.

In measles, as in other febrile diseases, of the madder-plant. See Rubia. the symptoms generally suffer some remission towards the morning, returning however in the evening with increased severity.

The measles, even when violent, are not usually attended with a putrid tendency; hut it sometimes happens, that such a disposition prevails both in the course of the disease and at its termination.

In such cases petechiæ are to be observed interspersed among the eruptions, and these last become livid, or assume almost a black colour. Hemorrhages break out from different parts of the body, the pulse becomes frequent, feeble, and perhaps irregular, universal debility ensues, and the

patient is destroyed.

In those cases where there is much fever, with great difficulty of breathing, and other symptoms of pneumonic inflamma-tion, or where there is great debility with a tendency to putrescency, there will always be considerable danger; but the consequences attendant on the measles are in general more to be dreaded than the immediate disease; for although a person shall ensue.

Vin in drawing the ribs downwards. By means of its upper slip, it serves to turn the neck obliquely backwards, or to one side. SACRO-SCIATIC LIGAMENTS.

ligaments which connect the ossa innomi-

SACRUM. (So called from sacer, sacred; because it was formerly offered in SACRO COCCYGARUS. A muscle of the sacrifices.) Os sacrum. Os basilare. The os sacrum derives its name from its being SACRO LUMBALIS. Sacro-lumbaris of offered in sacrifice by the ancients, or percess, which becomes gradually smaller as it descends. At the superior part of the bone we observe two oblique processes, of a cylindrical shape, and somewhat concave, which are articulated with the last of the lumbar vertebræ. At the base of each of these oblique processes is a notch, which, with such another in the vertebræ above it, forms a passage for the twentyfourth spinal nerve. In viewing this bone, either before or behind, we observe four, and sometimes five holes on each side, situate at each extremity of the transverse lines which mark the divisions of the bone. Of these holes, the anterior ones, and of these again, the uppermost, are the largest, and afford a passage to the nerves. The posterior holes are smaller, covered with membranes, and destined for the same purpose as the former. Sometimes at the bottom of the bone there is only a notch, and sometimes there is a hole common to it and the os coccygis.

The cavi y between the body of this bone and its processes, for the lodgment of the spinal marrow, is triangular, and becomes smaller as it descends, till at length it terminates obliquely on each side at the lower part of the bone. Below the third division of the bone, however, the cavity is no longer completely bony, as in the rest of the spine, but is defended posteriorly only by a very strong membrane; hence a wound in this part may be attended with the most dangerous consequences. bone is articulated above, with the last lumbar vertebra: laterally, it is firmly united, by a broad irregular surface to the ossa innominata, or hip bone: and below it is joined to the os coccygis. In women the os sacrum is usually shorter, broader, and more curved, than in men, by which means the cavity of the pelvis is more enlarged.

Suffron of steel. A red oxide of iron.

SAGAPENUM. (The name is derived from some eastern dialect.) Serapinum It is conjectured that this concrete gumminesinous juice is the production of an oriental umbelliferous plant. Sagapenum is brought from Persia and Alexandria in large masses, externally yellowish, internally paler, and of an horny clearness. It is falliaceous and fetid kind, and its virtues are similar to those which have been ascribed to assafotida, but weaker, and consequently it is less powerful in its effects.

SAGITAL SUTURE. (Sutura sagittalis, from sagitta, an arrow.) Sutura virgata, obelæa, rhabdoides. The suture which unites the two parietal bones. It has been named sagittal, from its lying between the coronal and lamdoidal sutures, as an arrow betwixt the string and the bow.

SAGITTARIA ALEXIPHARMACA. Malacca radix. Canna indica. Arundo indica. Arrow-root: dartwort.

SAGITTARIA SAGITTIFOLIA. (From ragitta, an arrow.) The systematic name of the common arrow-head, whose roots are esculent but not very nutritious.

SAGO. Sagus. Sagu. A dry fecula, obtained from the pith of a species of palm, the Cycas circualis of Linnzus, in the islands of Java, Molucca, and the Philipppines. The same substance is also brought from the West-Indies, but it is inferior to that brought from the East. Sago becomes soft and transparent by boiling in water, and forms a light and agreeable liquid, much recommended in febrile, phthusical, and calculous disorders, &c. To make it palatable, it is customary to add to it, when boiled or softened with water, some lemon juice, sugar and wine.

SAL AMMONIAC. Murias ammoniæ. A saline concrete formed by the combination of the muriatic acid with ammonia. This salt is obtained from several sources. It is found in places adjacent to volcanoes.

1. It appears in the form of an efflorescence, or groups of needles, separate or compacted together, generally of a yellow or red colour, and mixed with arsenic and orpiment; but no use is made of that which is procured in this way.

2. In Egypt it is made in great quantities from the soot of camel's dung, which is burnt at Cairo instead of wood. This soot is put into large round bottles, a foot the crystallization of certain salts, the fixand a half in diameter, and terminating in atton and preservation of certain liquids, a neck two inches long. The bottles are naturally very subject to evaporation, &c. filled up with this matter to within four inches of the neck. Each bottle holds ammoniæ acetatis. about forty pounds of soot, and affords nearly six pounds of salt. The vessels are ammonia acetatis. put into a furnace in the form of an oven, so that only the necks appear above. A fire of camel's dong is kindled beneath it, and continued for three days and three nights. On the second and the third day the salt is sublimated. The bottles are quor ammonia acetata then broken, and the salt is taken out in cakes. These cakes, which are sent just as they have been taken out of the bottles in Egypt, are convex, and unequal on the one side; on the middle of this side they exhibit each a tuburcle, corresponding to the neck of the bottle in which it was prepared. The lower side is concave, and both are sooty.

3. In this country sal ammoniac is likewise prepared in great quantities. The volatile alkali is obtained from soot, bones, and other substances known to contain it. To this the sulphuric acid is added, and this vitrolic ammoniac is decomposed by muriate of soda or common salt in a double affinity. The liquor obtained in consequence of this decomposition contains sulphate of soda and muriate of ammonia. The first is crystallized, and the second sublimated so as to form cakes, which are

then exposed to sale.

Ammoniacal muriate has a poignant, acrid, and urinous taste. Its crystals are in the form of long hexahædral pyramids, a number of them are sometimes united together in an acute angular direction, so as to exhibit the form of feathers. M. Rome de Lille thinks the crystals of ammoniacal muriate to be octohadrons bundled together. This salt is sometimes, but not frequently, found in cubic crystals Soda murias. in the middle of the concave hollow part of the sublimated cakes. It possesses one singular physical property, a kind of ductility or elasticity, which causes it to yield under the hammer, or even the fingers, and makes it difficult to reduce it to a powder. Muriate of ammonia is totally volatile, but a very strong fire is requisite to sublime it. It is liable to no alteration from air; it may be kept for a long time without suffering any change; it dissolves very readily in water. Six parts of cold water are sufficient to dissolve one of the salt. A considerable cold is produced as the solution takes place, and this cold is still keener when the salt is mixed with ice. This artificial cold is happily applied to produce several phanomena which could not otherwise take place, such as the congelation of water on certain occasions, tartarisata.

SALEP. Salap. Salab. the Orchis morio of Linnans :- bulbis indivisis, nectarii labio quadrilobo crenulato, cornu obtuso, petalis dorsalibus reflexis. This farinaceous powder is imported from Turkey. It may be obtained from several other species of the same genus of plants. It is an insipid substance, of which a small quantity, by a proper management, converts a large portion of water into a jelly, the nutritive powers of which have been greatly over-rated. Salep forms a considerable part of the diet of the inhabitants of Turkey, Persia, and Syria. The emthod of preparing salep is as follows: The new root is to be washed in water, and the fine brown skin which covers it is to be separated by means of a small brush or by dipping the root in warm water, and rubbing it with a coarse linen cloth. roots thus cleaned, are to be spread on a tin plate, and placed in an oven, heated to the usual degree, where they are to remain six or ten minutes. In this time they will have lost their milky whiteness, and ac- the maxilla and the tongue, and pour out quired a transparency like horn, without any diminution of bulk. Being arrived at this state, they are to be removed in order to dry and harden in the air, which will has mixed with it, 1. SALICORNIA. The name of a genus of plants in the Linnaan system. Class.

Monandria. Order, Monogynia.

SALICORNIA EUROPEA. The systematic name of the jointed glass wort, which is gathered by the country people and sold for samphire. It forms a good pickle with vinegar, and is little inferior to the sam. phire.

SALINE SUBSTANCES. The num-See Potassa tar- ber of saline substances is very considerable; and they possess peculiar characters. by which they are distinguished from other substances. These characters are founded on certain properties, which it must be confessed, are not accurately distinctive The root of their true nature. All such substances, however, as possess several of the four following properties are considered as saline: 1. A strong tendency to combination, or a very strong affinity of composition; 2. A greater or lesser degree of sapidity; 3. A greater or lesser degree of solubility in water; 4. Perfect incombustibility.

Saliunca: See Nardus celtica.

SALIVA. (So called, a salino sapore, from its salt taste, or from oranos, spittle.) The fluid which is secreted by the salivary glands into the cavity of the mouth. The secretory organ is composed of three pair of salivary glands. 1. The parotid glands, which evacuate their saliva by means of the Stenonian duct behind the middle dens molaris of the upper jaw. 2. The submaxillary glands, which pour out their saliva through the Warthonian ducts on each side of the frenulum of the tongue by a narrow osculum. 3. The sublingular glands, situated between the internal surface of their saliva through numerous Riverian ducts at the apex of the tongue.

The saliva in the cavity of the mouth month, which exhales from the labial and genal glands. 2. A roscid vapour, from be secreted in twelve hours. During mas-tication and speaking the secretion is -foliis serratis glabris ovato lanceolatis, augmented, from the mechanical pressure petiolis dentato glandulosis. It manifests a of the muscles upon the salivary glands considerable degree of bitterness to the Those who are hungry secrete a great taste, and is very adstringent. It is requantity, from the sight of agreeable food. commended as a good substitute for Pevirtue, according to the experiments of the and of four or five years growth. trid in warm air, and gives off volatile has always failed with this bark. alkali.

Constituent Principles. Saliva appears to consist of water, albumen, ammoniacal salt, and animal earth. Of water, there is four-fifths given out by distillation. The albumen is detected by alcohol of wine. The ammoniacal salt is demonstrated by triturating quick lime with saliva; and the animal earth from salival calculus, and the

products of fire.

The use of the saliva is, 1. It augments the taste of the food, by the evolution of sapid matter. 2. During mastication, it mixes with, dissolves, and resolves into its principles, the food; and changes it into a pultaceous mass, fit to be swallowed: hence it commences chymification. 3. It moderates thirst, by moistening the cavity of the mouth and fauces.

SALIVAL DUCTS. The excretory ducts of the salival glands. That of the parotid gland is called the Stenonian duct; those of the submaxillary glands the Warthonian ducts; and those of the sublingual,

the Reverian ducts.

Those glands SALIVAL GLANDS. which secrete the saliva are so termed. See Saliva.

SALTS. See Saline substances. with respect to their chemical properties, are divided into two classes; into acid salts or acids, and into alkaline salts or alkalis; and from the mutual combination of these two arises a third class, viz. that of neutral salts

SALTS, ACID. These are distinguished by their sour taste when diluted with

See Acia. water.

SALTS, ALKALINE. These possess a urinous, burning, and caustic taste, turn the syrup of violets to a green, have a strong affinity for acids, dissolve animal substances, unite readily with water, combines with oils and fat, and render them miscible with water, dissolve sulphur, and

are crystallizable. See Alkali

SALTS, NEUTRAL. Secondary salts. Under the name of neutral or secondary salis are comprehended such matters as are composed of two primitive saline substances combined together. These salts are called neutral, because they do not possess the characters of primitive salts; that is to say, they are neither acid nor alkaline salts; such as Epsom salts, alum,

nitre, &c.

SALTS, PRIMITIVE. Simple salts. Under this order is comprehended those salts which were formerly thought to be simple or primitive, and which are occasionally called simple salts. The accurate experiments of the moderns have proved that these are for the most part compounded; but the term is retained with greater propriety when it is observed, that these salts compose, when united, salts which are termed secondary. These salts are never met with perfectly pure in nature, but require artificial processes to render them so. This order is divided into three genera, comprehending saline terrestrial substances, alkalis, and acids. See Neutral

SALTS, SECONDARY.

salts.

Saltwort. See Salsola kali.

SALVATELLA. (Salvatellu, sc. vena, from salus, health, because the opening of it was formerly thought to be of singular use in melancholy.) This vein runs along the little finger, unites upon the back of the hand with the cephalic of the thumb, and empties its blood into the internal and external cubical veins

SALVIA. (A salvendo.) 1. The name of a genus of plants in the Linnæan system. Class, Diandria. Order, Monogynia.

2. The pharmacopæial name of the

common sage. Elelisphacos. Salvia officinalis of Linnæus:-foliis lanceolata-ovatie integris crenulatis, floribus spicatis, calycibus acutis. In ancient times sage was celebrated as a remedy of great efficacy. as would appear from the following lines of the school of Salernita:

Cur moriatur homo, cui salvia crescit in

Contra vin mortis, non est medicamen in

Salvia salvatrix, naturæ conciliatrix.

Sulvia cum ruta faciant tibi pocula tuta. But at present it is not considered as an article of much importance. It has a fragrant strong smell; and a warm, bitterish, aromatic, taste, I ke other plants containing an essential oil. It has a remark. able property in resisting the putrefaction of animal substances, and is in frequent use among the Chinese as a tonic, in the form of tea, in debility of the stomach and newous system.

SALVIA HORTENSIS MINOR. The small sage, or sage of virtue. A variety of the officinal sage, possessing similar virtues.

The systematic SALVIA OPFICINALIS. name of the garden sage. See Salvia.

SALVIA SCLAREA. The systematic name of the garden clary, called horminum in the pharmacopæias. The leaves and seeds are recommended as corroborants and antispasmodics, particularly in leucorrhæas and hysterical weaknesses. They have a bitterish warm taste, and a strong smell, of the aromatic kind.

SAMBUCUS. (From subucca, Heb. 2 musical instrument formerly made of this tree.) 1. The name of a genus of plants in the Linnaan system. Class, Pentan-

dria. Order, Trigyma.

2. The pharmacopæial name of the elder-tree. Sambucus vulgaris. Sambucue arborea. Acte. Infelix lignum. Sumbucus nigra of Linnaus :- cymis quinque partitis, foliis pinnatis, caule arboreo. This indigenous plant has an unpleasant narcotic smell, and some authors have reported its exhalations to be so noxious, as to render it unsafe to sleep under its shade. The parts of this tree that are proposed for medicinal use in the pharmacopæias are the inner bark, the flowers, and the berries. The first has scarcely any smell, and very little taste; on first chewing, it impresses a degree of sweetness, which is followed by a very slight but durable acrimony, in which its powers seem to reside. From its cathartic property it is recommended as an effectual hydragogue by Sydenham and Boerhaave; the former directs three handfuls of it to be boiled in a quart of milk and water, till only a pint remains, of which one half is to be taken night and morning, and repeated for seve-

rat days; it usually operates both upwards from sanguis, blood.) A natural function and downwards, and upon the evacuation of the body, by which the chyle is changed it produces, its utility depends. Boerhaave into blood. The uses of sanguification gave its expressed juice in doses from a are the generation of blood, which serves drachm to half an ounce. In smaller doses to fill the blood-vessels, to irritate and stiit is said to be an useful aperient and de- mulate the heart and arteries, to generate obstruent in various chronic disorders, or cause heat, to secrete the humours, and The llowers have an agreeable flavour; to excite the vital action. and infusions of them, when fresh, are Sanguins. SANIES. Ichor. This term is sometimes applied to a thin, limpid, and greenish discharge; and at other times to a thick and bloody kind of pus.

SANTALUM. (From zandal, Arab.) The name of a genus of plants in the Lin-

næan system. Saunders.

SANTALUM ALBUM. The systematic name of the yellow saunders. See Santalum citrinum.

SANTALUM ALBUM. The white saunders of the shop is said to be the alburnum of the tree whose medullary part is called Santalum citrimum.

SANTALUM CITRINUM. Santalum pullidum. Yellow saunders. Santalum album of Linnæus. White saunders wood is of a pale white eolour, often with a yellowish tinge, and, being destitute of taste or odour, it is superseded by the santalum citrinum, which is of a brownish yellow colour, of a bitterish aromatic taste, and of a pleasant smell, approaching to that of the rose. Both kinds are brought from the East Indies in billets, consisting of large thick pieces, which, according to Rumphius, are sometimes taken from the same, and sometimes from different trees. For though the white and yellow saunders are the wood of the same species of tree, yet the latter, which forms the central part of the tree, is not always to be found in sufficient quantity to repay the trouble and expense of procuring it especially, unless the trees be old; while the white, which is the exterior part of the wood, is always more abundant, and is consequently much cheaper.

Yellow saunders, distilled with water, yields a fragrant essential oil, which thickens in the cold into the consistence of a balsam, approaching in smell to ambergris, or a mixture of ambergris and roses; the remaining decoction, inspissated to the consistence of an extract, is bitterish and slightly pungent. Rectified spirit extracts, by digestion, considerably more than water; the colour of the tincture is

Dodecatheon. Symphytum pe- a rich yellow. The spirit distilled off is slightly impregnated with the fine flavour of the wood; the remaining brownish extract has a weak smell, and a moderate balsamic pungeney.

The wood is valued highly on account of its fragrance, hence the Chinese are said to fumigate their elothes with it, and to burn it in their temples in honour of their gods. Though still retained in the Materia Medica of the Edinburgh Pharmacopæia, it cannot be thought to possess any consider. able share of medicinal power. Hoffman eonsiders its virtues as similar to those of

restorative.

ed it in the character of a corroborant and SANTALUM PALLIDUM. See Santalum cit-

ambergris; and some others have esteem-

SANTALUM RUBRUM. Red saunders. Ptercarpus santalinus of Linnæus. There is some reason to believe that several red woods, eapable of communicating this colour to spirituous liquors, are sold as red saunders; but the true officinal kind appears, on the best authority, to be of this tree, which is extremely hard, of a bright garnet red colour, and bears a fine polish. It is only the inner substance of the wood that is used as a colouring matter, and the more florid red is mostly esteemed. being cut it is said to manifest a fragrant odour, which is more especially in old trees. According to Lewis, this wood "is of a dull red, almost blackish colour on the outside, and a deep brighter red within; its fibres are now and then curled, as in knots. It has no manifest smell, and little or no taste; even of extracts made from it with water, or with spirit, the taste is not considerable.

To watery liquors it communicates only a yellowish tinge, but to rectified spirit a fine deep red. A small quantity of an extract made with this menstroum, tinges a large one of fresh spirit of the same colour; though it does not, like most other resinous bodies, dissolve in expressed oils. Cf distilled oils, there are some, as that of lavender, which receive a red tineture from the wood itself, and from its resinous extract, but the greater number do not. Red saunders has been esteemed as a medicine; but its only use attaches to its colouring property. The juice of this tree, like that of some others, affords a species of sanguis draeonis.

Santolina. (From santalum, saunders, because it smells like the saunders wood.)

See Abrotamım fiemina.

SANTOLINA CHAMÆ-CYPARISSUS. The systematie name of the lavender cotton. See Abrotanum fæmina.

SANTONICUM. (From Santonia, its native place.) This plant and its seeds have received several names. Absinthium antonicum Alexandrinum. Sementina. Ab- Its virtues, according to Bergius, are desinthium seriphium Egytium Scheba Ara- tergent, resolvent, and aperiont, and its rum semina. Cina. Semen contra. The systematic SAPINDI'S SAPONARIA. name of the plant which affords soap-nuts.

See Suponuriæ muculæ.

SAPO. Soap. A composition of oils, or fats, with an alkalı The medicinal soap, sapo duras, sopo amygdatinus, is made withoil of sweet almonds, and half its weight of potash or caustic alkalı. Common or soft soap, sapo mollis, is made of tallow; Spanish, or Castile soap, of oil of almouds, and soda, or barilla. Black soap is a composition of train oil and an alkali; and green soap of hemp, linseed, or rape oil. The sape ex oleo olive et nutro confectus of the former London Pharmacopæia, or the sapo albus crispanus of the Edinburgh Pharmacapæia, (white Spanish soap,) being made of the finer kinds of olive oil, is the best, and therefore preferred for internal use. Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aretxus and others inform us, that the Greeks obtained their knowledge of its medical use from the Romans.

Zedoariæ sem. Xantolina. Lumbrico- use recommended in jaundices, gout, calflexis, floribus quinquefloris. The seeds on this complaint; and it has also been are small, light, and oval, composed of thought of use in supplying the place of a number of thin membranous coats of bile in the prime vize. The utility of this from the Levant shave a moderately strong jaundice, since it is now known, that gall-and not agreeable smell, somewhat of the stones have been found in many after wormwood kind, and a very bitter sub-acrd taste. Their virtues are extracted several months, and even years. Of its both by watery and spirituous menstrua, good effects in urinary calculous affections, They are esteemed to be stomachie, emmenagogue, and anthelmintic; but it is cally when dissolved in lime-water, by especially for the last-mentioned powers that they are now administered, and from their efficacy in this way they have obtained the name of wormseed. To admits supposes to be the chief agent in the forthe dose in substance is from one to two deadling twice a day. Lewis thinks that the incipient state of the disease that these drachms, twice a day. Lewis thinks that the incipient state of the disease that these the spirituous extract is the most eligible remedies promise effectual benefit, though preparation of the santonicum, for the they generally abate the more violent symptoms, where they cannot remove the With Boerhaave, soap was a genecause. visible.) The large vein of the leg, which ral medicine; for as he attributed most ascends along the little toe over the complaints to viscidity of the fluids, he, external ankle, and evacuates part of the and most of the Boerhaavian school, preblood from the foot into the popliteal scribed it, in conjunction with different resinous and other substances, in gout, rheumatism, and various visceral complaints. Soap is also externally employed as a resolvent, and gives name to several officinal preparations.

SAPO TEREBINTUINE. Starkey's soap. " R. Kalı præparati calidi, 3j. Olei terebinto. Zoii." The hot kali præparatum is to have the oil of turpentine gradually blended with it, in a heated mortar. Indolent swellings were formerly rubbed with this application, and perhaps some chronic affections of the joints might still

be benefited by it.

SAPONARIA. (From sapo, soap; so called because its juice, like soap, cleans clothes.) 1. The name of a genus of plants in the Linnæan system. Class, Decandria.

Order, Digynia.

2. The pharmacopoial name of the soapwort. Bruise-wort. Struthium Lanaria. Lychnis sylvestris. Ibixuma. The root of this plant Saponaria officinalis of Linnaus :-Calycibus cylindricis, foliis ovato-lanceolatis, is employed medicinally; it has no peculiar smell; its taste is sweetish, glutinous, and somewhat bitter. On being chewed for some time, it is said to discover a degree of acrimony, which continues to affect the mouth a considerable time. According to

Neuman, two ounces of the root yielded eleven drachms of watery extract; but seeds are sometimes given in the form of Cartheuser, from a like quantity, only obtained six drachms and twenty four grains. This extract manifested a sweetish taste, followed by an acrid quality The spirituous extract is less in quality, but of a more penetrating acrid tas e. Decoctions of the root, on being sufficiently agitated, produce a saponaceous froth, a similar soapy quality is observable also in the extract, and still more manifestly in the leaves, insomuch that they have been used by the mendicant monks as a substitute for soap in washing of their clothes, and Bergius, who made several experiments with the saponaria, declares that it had all the ef- lour. fects of soap itself.

From these peculiar qualities of the saponaria, there can be little doubt of its possessing a considerable share of medical efficacy, which Dr. Woodville says he could wish to find faithfully ascertained.

The diseases for which the saponaria is recommended, as syphilis, gout, rheumatism, and jaundice, are not, perhaps, the complaints in which its use is most availing; for a fancied resemblance of the roots of saponaria with those of sarsaparilla, seems to have led physicians to think them similar in their effects; and hence they have both been administered with the same intentions, particularly in fixed pains, and venereal affections. Bergius says, "in arthritide, cura mercuriale, &c. nullum aptiorem potum novi." However, according to several writers, the most inveterate cases of syphilis were cured by a decoction of this plant, without the use of

Haller informs us, that Boerhaave entertained an high opinion of its efficacy in jaundice, and other visceral obstructions.

SAPONARIA NUCULA. Bacca bermuden-A spherical fruit, Soap-berries. about the size of a cherry, whose cortical part is yellow, glossy, and so transparent as to shew the spherical black nut which rattles within, and which includes a white kernel. It is the produce of the Sapindus saponuria of Linnans, which grows in Jamaica. It is said that the cortical part of this fruit has a bitter taste, and no smell; that it raises a scapy froth with water, and has similar effects with soap in washing; that it is a medicine of singular and specific virtue in chlorosis. They are not known in the shops of this country.

SAPONARIA OFFICINALIS. The systematic name of the soap-wort. See Saponaria. SAPONULES. Saponuli. Combinations of the volatile or essential oils with different bases; as saponule of alumine.

volatile or essential oils with different arids.

SAPOTA. The oval fruited sapota, whose emulsion in calculous complaints, is the Acrus sapota of Linnaus. It is a native of South America, and bears a fruit like an apple, which has, when ripe, a luscious taste, resembling that of the marmalade of quinces, whence it is called natural mar-

SAPPHARINA AQUA. Aqua cupri ammo. niati. Made by a solution of sal aminoniac in lime-water, standing in a copper vessel.

SAPPHIRE. A gem of a sky-blue co-

Saracens consound. See Virga aurea. SARCIUM. (Dim. of oags, flesh.) A carbuncle, or small fleshy excrescence.

SARCITES. (From oage, flesh.) anasarca.

SARCOCELE. (From oagk, flesh, and инан, a tumour.) Hernia carnosa. This is a disease of the body of the testicle, and, as the term implies, consists, in general, in such an alteration made in the structure of it, as produces a resemblance to a hard fleshy substance, instead of that fine, soft, vascular texture, of which it is, in a natural and healthy state, composed.

The ancient writers have made a great number of distinctions of the different kinds of this disease, according to its different appearances, and according to the mildness, or malignity of the symptoms with which it m y chance to be attended. Thus, the sarcocele, the hydro-sarcocele, the scirrhus, the cancer, the cara adnato ad testem, and the caro adnata ad vasa, which are really little more than descriptions of different states and circumstances of the same disease, are reckoned as so many different complaints, requiring a variety of treatment, and deriving their origin from a variety of different humours.

Every species of sarcocele consists primarily in an enlargement, induration, and obstruction of the vascular part of the testicle; but this alteration is, in different people, attended with such a viriety of circumstances, as to produce several different appearances, and to occasion the many distinctions which have been

If the body of the testicle, though enlarged, and indurated to some degree, be perfectly equal in its surface, void of pain, has no appearance of fluid in its tunica vaginalis, and produces very little uneasiness, except what is occasioned by its mere weight, it is usually called a simple sarcocele, or an indolent scirrhus; if, at SAPONULES, ACID. Combinations of the the same time that the testis is enlarged and hardened, there be a palpable accumulation of fluid in the vaginal coat, the disease has by many been named a hydrosurcocele; if the lower part of the sper- cavity of the tunica vaginalis; but the body matic vessels, and the epidydimis were of the testicle itself is formed into cells, enlarged, hard, and knotty, they supposed containing either a turbid kind of water, a it to be a fungous, or morbid accretion, bloody sanies, or a purulent totid matter. and called it the care adnata ad vasa; if the Sometimes the disorder seems to be merely testicle itself was unequalinits surface, but local, that is, confined to the testicle, at the same time not painful, they distin- not proceeding from a tainted habit, nor guish it by the title of caro adnata ad tes- accompanied with diseased viscera, the tem; if it was tolerably equal, not very parient having all the general appearances painful, nor frequently so, but at the same and circumstances of health, and deriving time hard and large, they gave it the ap- his local mischief from an external injury. pellation of an occult or benign cancer; if At other times, a pallid, leaden counteit was ulcerated, subject to frequent acute nance, indigestion, frequent nausea, choice pain, to hamorrhage, &c. it was known pains, sudden pargings, &c. sufficiently inby that of a malignant or confirmed can- dicate a vitiated habit, and diseased viscer. These different appearances, though cera, which diseased viscera may also distinguished by different titles, are really no more than so many stages (as it were) of the same kind of disease, and depend a great deal on several accidental circumstances, such as age, habit, manner of living, &c. It is true, that many people pass several years with this disease, under its most favourable appearances, and without encountering any of its worst; but, on the other hand, there are many, who, in a very short space of time, run through all its stages. They who are most conversant with it, know how very convertible its power of gluing together wounds) A mildest symptoms are into its most dread-concrete gummi-resinous jnice, supposed ful ones, and how very short a space of to be the produce of the Penæa mucronata time often intervenes between the one and the other.

There is hardly any disease affecting the human body which is subject to more variety than this is, both with regard to its first manner of appearance, and the changes

which it may undergo.

Sometimes the first appearance is a mere simple enlargement and induration of the body of the testicle; void of pain, without inequality of surface, and producing no uneasiness, or inconvenience, except what is occasioned by its mere weight. And some people are so fortunate to have it remain in this state for a very considerable length of trine of the muscles and soft parts. time without visible or material alteration. On the other hand, it sometimes happens, that very soon after its appearance in this mild manner, it suddenly becomes unequal the class locales, and order tumores of and knotty, and is attended with very acute pains darting up to the loins and back, but still remaining entire, that is, not bursting and omoganos, the navel.) A fleshy excresthrough the integuments. Sometimes the cence about the navel. fury of the disease brooks no restraint; but, making its way through all the membranes which envelope the testicle, it either produces a large, foul, stinking, phagedenic ulcer, with hard edges, or it thrusts forth a painful gleeting fungus, subject to frequent hæmorrhage

Sometimes an accumulation of water is made in the tunica vaginalis, producing that mixed appearance, called the hydro-

sarcocele.

Sometimes there is no fluid at all in the sometimes be discovered and felt

The progress also which it makes from the testis upward, toward the process, is very uncertain; the disease occupying the testicle only, without affecting the spermatic process, in some subjects, for a great length of time; while, in others, it totally spoils the testicle very soon, and, almost as soon, scizes on the spermatic

chord.

SARCOCOLLA. (From σαςξ, flesh, and xoxxa, gluc; because of its supposed of Linnaus. It is brought from Persia and Arabia in small grains of a pale yellow colour, having also sometimes mixed with them a few of a deep red colour. Its taste is bitter, but followed with some degree of sweetness. It has been chiefly used for external purposes, and, as its name imports, has been thought to agglutinate wounds and illers; but this opinion now no longer exists.

SAUCOEPIPLOCELE. Enlarged testicle, with rupture, containing omentum.

order of appearances.

to which some of the mistakes committed tor magnus and the gracilis, is inserted,

to be ascribed to it as its true cause.

Every experienced surgeon must, however, he aware, that very little of truth and reality exists in a representation of this kind. The contagious matter, and the mineral specific, may jointly produce, in certain habits of body, a new series of symptoms, which, strictly speaking, are not venereal, which cannot be cured by mercury, and which are sometimes more to be dreaded than the simple and natural effects of the venereal virus,

Some of the most formidable of these appearances may be sometimes removed by sarsaparilla, the venereal virus still remaining in the system; and, when the force of that poison has been completely subdued by mercury, the same vegetable is also capable of freeing the patient from what may be called the sequelæ of a mer- smell, and a sweetish, aromatic, subacrid curial course.

The root of the sarsaparilla is sometimes employed in rheumatic affections, tioned in the pharmacopoias; but the bark scrofula, and cutaneous complaints, where is the most fragrant, and thought to be an acrimony of the fluids prevail.

SARSAPAHILLA GERMANICA. the Carex arenaria of Linnxus, which grows plentifully on the sea coast, is so drug was formerly held in great estimation, termed, and it appears, that the carex and publications were professedly written disticha and hirtu have also been collected, on the subject, It is now, however, thought and their roots used indifferently instead of the true sarsaparilla. shire. There are two species of chalybeate of the measles, but which do not usually water found in this spot, and they differ attend on the scarlatina, or at least in any considerably in their composition, though high degree. they rise nearly contiguous to each other. The one is a simple carbonated chalybeate, similar to the Tunbridge water: the other, shiverings, alternated by fits of heat. The which is better known and more frequent- thirst is considerable, the skin dry, and ed, and more particularly distinguished as Scarborough water, has, in conjunction with the iron, a considerable admixture of a purging salt, which adds much to its value. The diseases in which it is ordered are similar to those in which Cheltenham water is prescribed, only it is necessary to increase the purgative effect of this water by adding similar salts. It is, therefore, chiefly as an alterative that this water can be employed in its natural state.

Scarborough has an advantage belonging to its situation which Cheltenham does not possess, that of affording an opportunity for sea-hathing, the use of which will, in many cases, much assist in the plan of cure for many of the disorders for which fever. On the departure of the effloresthe mineral water is resorted to.

SCARLATINA. (From scarlatto, a deep

has two species: 1. Scarlatina amplex, the

Some have asserted that scarlatina never more extensive observation has confuted

this opinion.

Scarlatina attacks persons of all ages, but children and young persons are most posteriorly serves as a defence to the tho-at which time it very often becomes a very prevalent epidemic. It is, beyond all

The one to which it bears the greatest SCAPULARIÆ ARTERIÆ. The sca- resemblance is the measles; but from this pulary arteries and veins are branches of it is readily to be distinguished by the absence of the cough, watery eye, running SCARBOROUGH WATER. A ferru- at the nose and sneezing, which are the ginous spring at Scarborough in Vork- predominant symptoms in the early stage

> It begins like other fevers, with languor, lassitude, confusion of ideas, chills and the patient is of en incommoded with

anxiety, nausea, and vomiting.

Soon after the appearance of these symptoms, a stiffness is perceived in the neck, accompanied with a soreness in the throat, and a difficulty and pain in swallowing. On inspecting the internal fauces, they are found very red, and more or less swelled. On the tonsils, velum pendulum palati and usula, the parts most affected with inflam. mation, there generally, not always, appears a number of small whitish or greyish specks or sloughs.

About the third day, the scarlet efflorescence appears on the skin, which seldom produces however any remission of the cence, which usually continues out only for three or four days, a gentle sweat comes same morbid appearances are to be obon, the fever subsides, the cuticle or scarfskin then falls off in small scales, and the patient gradually regains his former strength and health.

On the disappearance of the efflores- tina. cence in scarlatina, it is, however, no uncommon occurrence for an anasarcous swelling to affect the whole body, but this is usually of a very short continuance.

Scarlatina in several instances approaches very near to the cynanche maligna, and the patient is then seized not only with a coldness and shivering, but likewise with great languor, debility and sickness, succeeded by heat, nausea, vomiting of bilious matter, soreness of the throat, inflammation, and ulceration in the tonsils, a frequent and laborious breathing, and a quick and small depressed pulse. When the effloresecnce appears, which is usually on the third day, it brings no relief, on the contrary the symptoms are much aggrated, and fresh ones arise.

In the progress of the disease, one universal redness, unattended however by any pustular cruption, pervades the face, body, and limbs, which parts appear somewhat swollen. The eyes and nostrils partake likewise more or less of the redness, and in proportion as the former have an inflamed appearance, so does the tendency

to delirium prevail.

When scarlatina anginosa is to terminate in health, the fiery redness abates gradually, and is succeeded by a brown colour, and the skin becomes rough, peels off in small scales, the tumefaction subsides, and health is gradually restored. On the contrary, when it is to terminate fatally, the febrile symptoms run very high from the first of its attack, the skin is intensely hot and dry, the pulse is very frequent but small, great thirst prevails, the efflorescence makes its appearance on the second day, or sooner, and about the third or fourth is probably interspersed with large livid spots, and a high degree of delirium ensuing, or hamorrhages breaking out, the patient is cut off about the sixth or eighth day. In some cases a severe purging arises, which never fails to prove fatal. Some again, where the symptoms do not run so high, instead of recovering, as is usual, about the time the skin begins to regain its natural colour, fall into a kind of lingering way, and are carried off in the course of a few weeks,

Scarlatina of itself is not usually attended with danger, although a considerable degree of delirium sometimes prevails for a day or two; but when it partakes See Innominatum os. much of the nature of cynanche maligna, or degenerates into typhus putrida, which it is apt to do, it often proves fatal. Scelotyrbe. (From oxenos, the leg, and Tuesn, riot, intemperance.) A debility of the legs from scurvey or an intemperate way of life.

SCHEROMA. A dryness of the eve from the want of the lacrymal fluid. The effects of this lacrymal fluid being deficient, the eyes become dry, and in their motions produce a sensation as though sand, or some gritty substances, were between the eye and the eyelid; the vision is obscured, the globe of the eye appears foulish and dull, which is a bad omen in acute diseases. The species are, 1. Scheroma febrile, or a dryness of the eyes, which is observed in fevers, complicated with a phlogistic density of the humours. 2. Scheroma exhaustorum, which happens after great evacuations, and in persons dying. 3. Scheroma inflammatorum, which is a symptom of the ophthalmia sicca. 4. Scheroma itinerantium, or the dryness of the eyes, which happens in sandy places to travellers, as in hot Syria, or from dry winds, which dries up the humidity necessary for the motion of the eyes.

Schidacedon. (From σχιδαξ, a splinter.) A longitudinal fracture of the bone. SCHINELAUM. (From oxivos, the mastich, and sharr, oil.) Oil of mastich.

(From sheque, Heb.) This amphibious animal is of the lizard kind, and caught about the Nile, and thence brought dried into this country, remarkably smooth and glossy, as if varnished. The flesh of the animal, particularly of the belly, has been said to be diuretic, alexipharmic, aphrodisac, and useful in leprous disorders.

Scirrhoma. (From origgow, to harden.)

Scirrhosis. A hard tumour See Scirrhus. SCIRRHUS. (From oxiggow, to harden.) A genus of disease in the class locales, and order tumores of Cullen; known by a hard tumour of a glandular part, indolent, and not readily suppurating. The following observations of Mr. Pearson are deserving of attention. A scirrhus, he says, is usually defined to be a hard, and almost insensible tumour, commonly situated in a glandular part, and accompanied with little or no discolouration of the surface of nature of the disease; and as glands in the skin. This description agrees with the their healthy state are not endowed with true or exquisite scirrhus; but when it has proceeded from the indolent to the malignant state, the tumour is then unequal in its figure, it becomes painful, the skin acquires a purple or livid hue, and the cutaneous veins are often varicose. Let us now examine whether this enumeration of ptoms alone can yield no certain information symptoms be sufficiently accurate for practical purposes.

It is probable, that any gland in the living body may be the seat of a cancerous disease; but it appears more frequently as an idiopathic affection in those glands that form the several secretions than in the absorbent glands: and of the secreting organs, those which ment which we find to be successful in separate fluids that are to be employed in scrophula; and when they prove unconthe animal economy, suffer much oftener querable by the powers of medicine, we than the glands which secrete the excre- generally see them continue stationary and mentitious parts of the blood. Indeed, it innocent to the latest period of life. Wrimay be doubted whether an absorbent ters have indeed said much about certain gland be ever the primary seat of a true tumours changing their nature, and assumscirrhus. Daily experience evinces, that ing a new character; but I strongly susthese glands may suffer contamination from pect that the doctrine of the mutation of

but under such circumstances, this morbid alteration being the effect of a disease in that neighbouring part, it ought to be regarded as a secondary or consequent affection. I never yet met with an unequivocal proof of a primary scirrhus in an absorbent gland; and if a larger experience shall confirm this observation, and establish it as a general rule, it will afford material assistance in forming the diagnosis of this disease. The general term scirrhus hath been applied, with too little discrimination, to indurated tumours of lymphatic glands. When these appendages of the absorbent system enlarge in the early part of life, the disease is commonly treated as strumous; but as a similar alteration of these parts may, and often does occur at a more advanced period, there ought to be some very good reasons for ascribing malignity to one rather than the other. In old people the tumour is indeed often larger, more indurated, and less tractable than in children; but when the alteration or ginated in the lymphatic glands, it will very rarely be found to possess any thing cancerous in its nature.

If every other morbid alteration in a part were attended with pain and softness, then induration and defective sensibility might point out the presence of a scirrhus. But this is so far from being the case, that even encysted tumours, at their commencement, frequently excite the sensa-tion of impenetrable hardness. All glands are contained in capsulæ, not very elastic, so that almost every species of chronic enlargement of these bodies must be hard; hence this induration is rather owing to the structure of the part, than to the peculiar much sensibility, every disease that gradually produces induration, will rather diminish than increase their perceptive powers. Induration and insensibility may therefore prove that the affected part does not labour under an acute disease; but these symconcerning the true nature of the morbid alteration. Those indolent affections of the glands that so frequently appear after the meridian of life, commonly manifest a hardness and want of sensation, not inferior to that which accompanies a true scirrhus; and yet these tumours will often admit of a cure by the same mode of treatdiseases into each other, stands upon a tion are commonly met with on a variety very uncertain foundation. Improper of other occasions, and in this particular treatment may, without doubt, exaspe- instance they may be the effects of the rate diseases, and re der a complaint which disease, but are not essentially connected appeared to be mild and tractable, dan- with its presence. gerous, or destructive; but to aggravate the symptoms, and to change the form of panied with a discolouration of the skin the disease, are things that ought not to be and a dusky redness, purple, or even livid confounded. I do not affirm, that a breast appearance of the surface, is commonly which has been the seat of a mammary seen when there is a malignant scirrhusabscess, or a gland that has been affected. The presence or abscence of colour can, ous; for they might have suffered from this precarious criterion of the true n ture of disease had no previous complaint existed; the complaint. When the disease is clearly but these morbid alterations generate no known, an altered state of the skin may greater tendency to cancer than if the assist us in judging of the progress it has parts had always retained their natural made; but as the skin may suffer similar condition. that one is convertible into the other.

Chirurgical writers have generally enumerated tumour as an essential symptom its stalks are hard and dry, Blanch.) vy.) Medicines for the scurvy.

SCORBUTUS. (From schorboet, Germ.) Gingibrachium, because the gums and arms, and gingipedium, because the gums and legs, are affected by it. The scurvy. A genus of disease in the class cachexia, and order impetigines of Cullen; characterised by extreme debility; complexion pale and bloated; spongy gums; livid spots on the skin; breath offensive; adematous swellings in the legs; hæmorrhages; foul ulcers; fetid urine; and extremely offensive stools. The scurvy is a disease of a putrid nature, much more prevalent in cold climates than in warm ones, and which chiefly affects sailors, and such as are shut up in besieged places, owing, as is supposed, to their being deprived of fresh provisions, and a due quantity of acescent food, assisted by the prevalence of cold and moisture, and by such other causes as depress the nervous energy, as indolence, confinement, want of exercise, neglect of cleanliness, much labour and fatigue, sadness, despondency, &c. These several debilitating causes, with the concurrence of a diet consisting principally of salted or putrescent food, will be sure to produce this disease. It seems, however, to depend more on a defect of nourishment, than on a vitiated state; and the reason that salted provisions are so productive of the scurvy, is, most probably, because they are drained of their nutritious juices, which are extracted and run off in brine. As the disease is apt to become pretty general amongst the crew of a ship when it has once made its appearance, it has been supposed by many to be of a contagious nature; but the conjecture scems by no means well founded.

A preternatural saline state of the blood has been assigned as its proximate cause. It has been contended by some physicians,

disease is a debilitated state of the solids. arising principally from the want of ali-

The scurvy comes on gradually, with heaviness, weariness, and unwillingness to move about, together with dejection of spirits, considerable loss of strength, and debility. As it advances in its progress, the countenance becomes sallow and bloated, respiration is hurried on the least motion, the teeth become loose, the gums are spongy, the breath is very offensive, livid spots appear on different parts of the body, old wounds which have been long healed up break out afresh, severe wandering pains are felt, particularly by night, the skin is dry, the urine small in quantity, turning blue vegetable infusions of a green colour; and the pulse is small, frequent, and, towards the last, intermitting; but the intellects are, for the most part, clear and distinct.

By an aggravation of the symptoms, the disease, in its last stage, exhibits a most wretched appearance. The joints become swelled and stiff, the tendons of the legs are rigid and contracted, general emaciation ensues, hæmorrhages break forth from different parts, fetid evacuations are discharged by stool, and a diarrhea or dysentery arises, which soon terminates the tragic scene.

Scurvy, as usually met with on shore, or where the person has not been exposed to the influence of the remote causes before enumerated, is unattended by any violent symptoms, as slight blotches, with scaly eruptions on different parts of the body, and a sponginess of the gums, are the chief ones to be observed.

In forming our judgment as to the event of the disease, we are to be directed by the violence of the symptoms, by the situation of the patient with respect to a vegetable diet, or other proper substitutes, by his former state of health, and by his constitution not having been impaired by previous diseases.

Dissections of scurvy have always discovered the blood to be in a very dissolved The thorax usually contains more or less of a watery fluid, which, in many cases, possesses so high a degree of acrimony, as to excoriate the hands by coming in contact with it; the cavity of the abdomen contains the same kind of fluid; the lungs are black and putrid; and the heart itself has been found in a similar state, with its cavity filled with a corrupted fluid. In many instances, the epiphyses have been found divided from the bones, the cartilages separated from the ribs, and srveral of the bones themselves dissolved by caries. The brain seldom shows any marks of disease.

Scordium. (From oxopodov, garlic; so that the primary morbid affection in this called because it smells like garlic.) Tris-

cago palustris. redolens. Water germander. plant have a smell somewhat of the garlic kind, from which dirennistance it is supposed to take its name: to the taste they are bitterish and slightly pungent. The plant was formerly in high estimation, but is now justly fallen into disuse, although recommended by some in antiseptic cataplasms and fomentations.

Scourieurs. See Scorpioides.

SCORZONERA. (From escorza, a serpent, Span.; so called because it is said to be effectual against the bite of all venemous animals.) 1. The name of a genus of plants in the Linnaan system. Class, Syngenesia. Order, Polygamia æquales.

2. The pharmacoperial name of the plant called also escorzonera. Viperuria. Serpentaria hispanica. Goats' grass. Vipers' grass. The roots of this plant, Scorzonera humilis of Linnaus :- cante falundo, unificro; foliis lato lanccolatis, nervosis, planis, has been sometimes employed medicinally as alexipharmics, and in hypochondriacal disorders, and obstructions of the viscera. The Scorzonera hispanica mostly supplies ple, we very frequently meet with gout in the shops, whose root is esculent, oleraceous, and against diseases inefficacious.

Scorzonera hispanica. The systematic name of the esculent vipers' grass.

SCORZONERA HUMILIS. The systematic name of the officinal vipers' grass. See Scorzonera.

SCOTODINE. (From oxotos, darkness, and fives, a giddiness.) Scotodinia. Scotodinos. Scotoma. Scotomia. Giddiness with impaired sight.

SCROBICULUS CORDIS. (Dim. of scrobs, a ditch.) The pit of the stomach.

SCROFULA. (From scrofu, a swine; because this animal is said to be much subject to a similar disorder.) Scrophula. Charas. Ecrnelles, Fr. Struma. Coiras. Scrophula. The king's evil. A genus of usually some time in the winter and spring, disease in the class cachexia, and order impetigines of Cullen He distinguishes four ed, in summer and autumn. The first apspecies. 1. Scrophula vulgaris, when it is pearance of the disorder is commonly in without other disorders external and permanent. 2. Scrophula mesenterica, when internal, with loss of appetite, pale coun- discolouration. These appear, in general,

Chamædrys palustris allium tenance, swelling of the belly, and an un-Teucrium usual foctor of the excrements. 3. Scroscordium of Linnaus. The leaves of this phula fugax. This is of the most simple kind; it is seated only about the neck, and for the most part is caused by the resorption from sores on the head. 4. Scrophula Americana, when it is joined with the yaws. Scrophula consists in hard indolent tumours of the conglobate glands in various parts of the body; but partieularly in the neck, behind the ears, and under the chin, which after a time suppurate and degenerate into ulcers, from which, instead of pus, a white curdled matter, somewhat resembling the coagu-

lum of milk, is discharged

The first appearance of the disease is most usually between the third and seventh year of the child's age; but it may arise at any period between these and the age of puberty; after which it seldom makes its first attack. It most commonly affects children of a lax habit, with smooth fine skins, fair hair, and rosy cheeks. It likewise is apt to attack such children as shew a disposition to rachitis, and marked by a protuberant forehead, enlarged joints, and a tumid abdomen. Like this disease, it seems to be peculiar to cold and variable climates, being rarely met with in warm ones. Scrophula is by no means a contagious disease; but, beyond all doubt, is of an hereditary nature, and is often entailed by paren's on their children. There are, indeed, some practitioners who wholly deny that this, or any other disease, can be acquired by an hereditary right; but that a peculiar temperament of body, or predisposition in the constitution to some diseases, may extend from both father and mother to their offspring, is, observes Dr. Thomas, very clearly proved. For examyoung persons of both sexes, who could never have brought it on by intemperance, sensuality, or improper diet, but must have acquired the predisposition to it in this way.

Where there is any predisposition in the constitution to scrophula, and the person happens to contract a venereal taint, this frequently excites into action the causes of the former; as a venereal bubo not unfrequently becomes scrophulous, as soon as the virus is destroyed by mercury. The late Dr. Cullen supposed scrophula to depend upon a peculiar constitution of the lymphatic system. The attacks of the disease seem much affected or influenced by the periods of the seasons. They begin and often disappear, or are greatly amendthat of small oval or spherical tumours under the skin, unattended by any pain or

5 A

upon the sides of the neck, below the ear, lungs, with hectic fever, arise, the conseor under the chin; but, in some cases, the joints of the elbows or ankles, or those of the fingers and toes, are the parts first af- have died of this disease, many of the visfected. In these instances, we do not, however, find small moveable swellings; but, on the contrary, a tumor almost uniformly surrounding the joint, and interrupting its motion.

After some length of time the tumors become larger and more fixed, the skin which covers them acquires a purple or livid colour, and, being much inflamed, they at last suppurate and break into little holes, from which, at first, a matter somewhat puriform oozes out; but this changes by degrees into a kind of viscid serous discharge, much intermixed with small pieces of a white substance, resembling the curd of milk.

The tumors subside gradually, whilst the ulcers at the same time open more, and spread unequally in various directions. After a time, some of the ulcers heal; but aquatica. other tumors quickly form in different parts of the body, and proceed on, in the same slow manner as the former ones, to suppuration. In this manner the disease goes on for some years, and appearing at last to have exhausted itself, all the ulcers heal up, without being succeeded by any fresh swellings; but leaving behind them an ugly packering of the skin, and a scar of nel-wort. The root and leaves of this considerable extent. This is the most mild plant, Scrophularia nodosa of Linnaus:form under which scrophula ever appears. foliis cordatis, trinervatis; caule obtusan. In more virulent cases, the eyes are par- gulo, have been celebrated both as an ticularly the seat of the disease, and are internal and external remedy against inaffected with ophthalmia, giving rise to flammations, the piles, scrophulous tuulcerations in the tarsi, and inflammation mors, and old ulcers; but they are now of the tunica adnata, terminating not un- only used in this country by the country frequently in an opacity of the transparent people

fected, they swell and are incommoded by dominial viscus or viscera into the scrotum. excruciating deep-seated pain, which is See Hernia. much increased upon the slightest motion. The swelling and pain continue to increase, the muscles of the limb become at length much wasted, Matter is soon afterwards formed, and this is discharged at small openings made by the bursting of the skin. Being, however, of a peculiar acrimonious nature, it erodes the ligaments and cartilages, and produces a caries of the neigh- small stone ) A scruple or weight of 20 bouring bones. By an absorption of the matter into the system, hectic fever at last arises, and, in the end, often proves fatal.

When scrophula is confined to the external surface, it is by no means attended with danger, although on leaving one part, it is apt to be renewed in others; but when the ulcers are imbued with a sharp acrimony, spread, erode, and become deep, without sis. shewing any disposition to heal; when deep seated collections of matter form tensis. amongst the small bones of the hands and feet, or in the joints, or tubercles in the rina.

quences will be fatal.

On opening the bodies of persons who cera are usually found in a diseased state. but more particularly the glands of the mesentery, which are not only much tunefied, but often ulcerated. The lungs are frequently discovered bent, with a number of tubercles or cysts, which contain matter of various kinds. Scrophulous glands, on being examined by dissection, feel somewhat softer to the touch than in their natural state, and when laid open, they are usually found to contain a soft curdy matter, mixed with pus.

SCROPHULARIA. (From scrofula, the king's evil; so called from the unequal tubercles upon its roots, like scrophulous tumors.) The name of a genus of plants in the Linnzan system. Class, Didynamia. Order, Angiospermia. The fig-wort.

Thus the liver titious nature; the nature of these bottle- retains the constituent principles of bile kind of glands is turned towards the parts contained in the blood of the vena porta, to which the mucous membrane adheres, elaborates, combines them, and forms the their mouth or neck opens on the surface bile, and animal fluid, distinguishable by contiguous to these membranes.

glands discharge themseives are easy to be contains the elements which enter into its perceived on the amygdalæ, mucous sur-

face of the urethra, rectum, &c.

Secretion and excretion are facilitated by the irritation occasioned by the presence of air, aliment, or urine; by the compression induced by them, and, finally, by the peristaltic contractions of the muscular fibres to which mucous membranes adhere throughout the whole extent of the

The fluids, which are considerably different from the blood, require for their secretion organs of a more complicated structure; these are called conglomerate glands with health, escape observation, while to distinguish them from hymphatic glands, those which are more complete, and dewhich are named conglobate. These glands are visceral masses, formed by an assemblage of nerves and every species of vessels, disposed in packets, and united by cellular structure; a proper membrane, or an elongation of that which lines the cavity that includes them, surrounds their external surface, and separates them from the circumjacent parts.

The arteries do not form an immediate continuation with their excretory ducts, as Rysch affirmed; nor do there exist immediate glands between these vessels as Malpigli believed; it seems more probable that each gland has its cellular or parenchymatous substance in the areola, into which the arteries pour the materials of Barden observed, are asleep or awake

secreted liquor, carrying it into recepta. After serous transudation, requiring only cles, where it accumulates, while the other receives that part which the action of the organ could not completely elaborate, or the residue of the secretion.

The nerves which always enter more or pathetics, terminate variously in their substance, and furnish each of them with a particular sensibility, by means of which they distinguish in the blood brought thither by the vessels the constituent parts or macertain characteristic properties that are The apertures by which the mucous subject to variations according as the blood composition in a greater or less degree; according to the increased or diminished disposition of the gland to retain them, and to effect a more or less complete mixture of them. The qualities of the bile dependent on the concurrence of all these circumstances, should present so many differences as the blood contains principles, and as the hepatic organ may offer varieties relative to the composition of the former, and degree of activity of the latter. Hence arise alterations of the bile, the most inrange the natural order of the functions, become evident by diseases of which they may be sometimes considered the effect, and at other times the cause. These alterations of the bile (and what is here said of the secretion of this humour may extend to almost every other secretion of the animal economy) never extend so far as to prevent it from being distinguished; it always preserves in a greater or less degree its essential and primitive characters, it never acquires the qualities of another liquor so as to resemble serum, urine, or saliva, &c.

The action of secretory glands is not continual, most of them are subject to the alternate state of action and rest, all, as the fluid they prepare; in consequence of a when any irritation operates on them, or

mastication, &c.

tion, the surrounding parts, or such as are situated in its vicinity, for instance, the vey, not as one of the membranes of the liver, is comprised in the sphere of action of the duodenum, since the repletion of this intestine irritates it, determines a more branes of the ovum, at the full period of abundant afflux of humours, and a more copious secretion of bile.

A sensation by which we perceive bodies around us, and their sen-The organ of sight is sible qualities. formed of three parts perfectly distinct, which serve to protect the globe of the eye, to withdraw it suddenly from the influence of light, and to preserve it in a condition necessary for the exercise of these functions: These consist in the supercilia, palpebræ, and lachrymal passages, parts accessory to the organ. The eye-ball itself presents two portions very different from each other, one formed by almost the whole, and may be called an optic instrument; the other formed by a medullary expansion of the optic nerve is the immediate organ of sight, this is the retina, alone adapted to receive the impression of light, and to be affected by the delicate contact of this extremely subtle This impression or sensation is transmitted to the cerebral organ by the optic nerve, of which the retina is merely the expanded extremity.

The eye-brows, as being accessory organs to vision, have the effect of diminishing the effect of a too strong light by partly absorbing its rays. The supercilia answers this purpose better in proportion to the

of the hair; thus we knit the brow trans. versely in passing from dark to a lighted place, the strong light of which has a disa. greeable effect on the organ of sight. Hence arose the custom of certain south-SEDLITZ WATER. (From sedo, to assuage; so eye and its covering. The anterior part of the eye, thus defended against external injuries, is continually moistened by the tears, they also guard against the effects of friction, to which the eye is exposed. Eye.)

> Luminous rays, emanating from a light object, form a cone, the apex of which corresponds to the point of a body which we are looking at, and its base is applied to the anterior part of the cornea; all those rays which touch the mirror of the eye pass through it, experience a refraction proportioned to the density of the cornea, and to the convexity of this membrane, greater than that of the atmosphere: when approaching the perpendicular they pass through the aqueous humours less dense, and meet with the iris. All those rays which fall on this membrane are reflected, and shew its colour different in different individuals. It is only the most central rays that penetrate the pupil, and serve for sight: these enter the pupil in greater or less number, according as it may be more or less dilated. The pupil becomes larger or smaller conformable to the expansion or contraction of the iris. The motions of the iris depend entirely on the mode in which light affects the retina; it is of itself insensible to the impression of luminous rays, as proved by Fontana, who always found it immoveable when he directed rays of light exclusively to it.

The rays to which the pupil give passage pass through the aqueous humour of the posterior chamber; and soon come into contact with the crystalline lens, which powerfully refracts them, on account of its density and lenticular form. When more approaching the perpendicular by this body, they proceed as far as the retina, through the vitreous humour, that is less dense, and which preserves, without augmentation, the effect of the refraction proprojection formed, and the darker colour duced by the crystalline lens; the rays single point of the retina, and produce an means, without much trouble, he was impression that gives us an idea of certain enabled to acquire a fortune. power of refraction either from too great a convexity of the cornea or crystalline lens, or more considerable density of the humours and excessive depth of the globe of the eye, the luminous rays being united too soon, cross each other, again diverge, fall scattered on the retina, and produce only a confused sensation. In this disease of vision called myopia, patients can only distinguish very near objects, whence rays only observe with distinct objects, because the rays that come from them being very convergent, have not occasion to be much refracted. The sensibility of the retina is, under certain circumstances, so much raised, that the eye hardly supports the are called nyctalopes, who distinguish objects in the midsi of utter darkness, as a few rays are sufficient to affect their organ of vision. The eyes are not immoveable in the part they occupy, they are directed the former published his observations in towards all the objects of which we wish the Memoirs of the Academy of Sciences; muscles, and it is observed that there is printed in the Philosophical Transactions. such a correspondence of action in muscles Newman, therefore, was not the first who that move both eyes, that these organs turn made known the composition of Seignette's at the same time towards the object, so salt, in his treatise on salt-petre; for that the visual axes are exactly parallel.

of the fruit of any vegetable.

2. The seed or prolific liquor secreted in the testicles, and carried through the epididymis and vas deferens into the vesiculæ seminales, to be emitted sub coitu into the female vagina, and there, by its aura, to penetrate and impregnate the ovulum in the ovarium.

In castrated animals, and in eunuchs, the vesiculæ seminales are small, and contracted; and a little lymphatic liquor, but the oxygenated acid of salt, by which it is no semen, is found in them. The semen is coagulated in the form of white flakes. It detained for some time in the vesiculæ is also acted upon by alcohol of wine. seminales, and rendered thicker from the continual absorption of its very thin part, small portion of empyreumatic oil, and

In lascivious men, the semen is sometimes, though rarely, propelled by nocturnal pollution from the vesiculæ seminales, through the ejaculatory ducts, (which arise from the vesiculæ seminales, perforate the urethra transversely, and open themselves by a narrow and very nervous mouth at the sides of the caput gallinaginis,) into the uvethra, and from it to some distance. But in chaste men the greatest part is again gradually absorbed from the vesicula seminales through the lymphatic vessels, and conciliates strength to the body. The gland, surrounded by the four clinoid pro-ccsses. The same odour is observed in the roots of the orchis, julæ of chesnuts, and the anthere of many plants. The smell of the semen of quadrupeds, when at heat, is so penetrating as to render their flesh fetid and useless, unless castrated. Thus the

Colour. In the testicles it is somewhat The usual and in an atrabiliary young man, black.

Quality. Semen exposed to the atmospheric air, loses its pellucidity, and becomes thick, but after a few hours it is again rendered more fluid and pellucid than it was immediately after its emission. This phenomenon cannot arise from water or oxygen attracted from the air. At SEMEN. 1. The seed, kernel, or stone length it deposits a phosphorated calx,

and forms a corneous crust.

Experiments with semen prove that it turns the syrup of violets green, and dissolves earthy, mediate, and metallic salts. Fresh semen is insoluble in water, until it has undergone the above changes in atmospheric air. It is dissolved by alkaline salts. By atherial oil it is dried noto a pellucid pellicle, like the cortex of the brain. It is dissolved by all acids except

SEMIMEMBRANOSUS. cients was called aura seminis.

Use. 1 Emitted into the female vagina long head of the biceps, and afterwards sub coitn, it possesses the wonderful and stupendous power of impregnating the ovulum in the female ovarium. The odorous principle, or aura spermatica only, in a short tendon, which is inserted chiefly appears to penetrate through the cavity of into the upper and back part of the head the uterus and fallopian tubes to the female of the tibia, but some of its fibres are ovarium, and there to impregnate the albuspread over the posterior surface of the minous latex of the mature ovulum by its capsular ligament of the knee. Between this capsular ligament and the tendon of the muscle, we find a small bursa mucoseminal aura. 2. In chaste men, the se- sa. The tendons of this and the last described muscle form the inner ham-string. This muscle bends the leg, and seems likewise to prevent the capsular ligament from being pinched

SEMI-ORBICULARIS ORIS. See Orbicularis oris.

SEMI-SPINALIS COLLI. Semi spinalis sive transverso-spinalis colli of Winslow, Spinulis cervicis of Albinus, Spinulis colli of Douglas, Transversalis colli of Cowper, and Transverso-spinal of Dumas. A muscle situated on the posterior part of the neck, which turns the neck obliquely backwards, and a little to one side. arises from the transverse processes of the uppermost six vertebræ of the back by as many distinct tendons, ascending obliquely under the complexus, and is inserted into the spinous processes of all the vertebræ of the neck, except the first and last.

SEMI-SPINALIS DORSI nalis externus seu transverso spinalis dorsi of Winslow. Semi spinatus of Cowper, and Transverso-spinal of Dumas. A muscle situated on the back, which extends the spine obliquely backwards. It arises from the transverse processes of the seventh, eighth, ninth, and tenth vertebræ of the the organ of hearing, and are situated in back, by as many distinct tendons, which soon grow fleshy, and then become tendinous again, and are inserted into the spinous processes of all the vertebræ of the back above the eighth, and into the lowermost of the neck, by as many tendons.

5 B

SEMI-SPINALIS EXTERNUS. See Semi-spinalis dorsi.

SEMI SPINATUS. See Semi-spinalis darsi.

SEMI-TENDINOSUS. This muscle, which is the semi-nervosus of Douglas and Winslow, and Ischio-creti tibial of Dumas, is situated obliquely along the back part of the thigh. It arises tendinous and fleshy from the inferior, posterior, and outer part of the tuberosity of the ischium, in common. with the long head of the biceps crunis, to the posterior edge of which it continues to adhere, by a great number of oblique fibres, for the space of two or three inches. Towards the lower part of the os femoris, it terminates in around tendon, which passes behind the inner condyle of the thigh bone, and becoming flat, is inserted into the upper and inner part of the ridge of the tibia, a little below its tuberosity. This tendon sends off an aponeurosis, which helps to form the tendinous fascia that covers the muscles of the leg. This muscle assists in bending the leg, and at the same time draws it a little inwards.

SEMPERVIVUM. (From semper, always, and vivo, to live; so called because it is always green.) 1. The name of a genus of plants in the Linnzan system. Class, Dodecandria. Order, Polygynia.

2. The pharmacopæial name of some plants. See Sedum majus

SEMPERTIVUM ACRE. The stone-crooccasionally so termed See Illecebra. The stone-crop is

SEMPERVIVUM TECTORUM. The systematic name of the house-leek. See Sedum majus.

SENECIO. (Senecia from senesco, to grow old; so called because it has a greyish down upon it, like the beard of old men.) 1. The name of a genus of plants in the Linnxan system. Class, Syngenesia, Order, Polygamia superflua.

2. The pharmocopæial name also of the groundsel. See Erigerum.

SENECIO VULGARIS. The systematic name of groundsel. See Erizerum.

SENECIO JACOBÆA The systematic name

of the ragwort. See Jacobaa.

SEVECTA ANGUIUM. The cast skin of a serpent; its decoction is said to cure deafness.

SENEGA. See Seneka.

SENEGA GUM. See Gummi senegalense. Senegaw milkwort. See Seneka.

SENEKA. (So called because the Senecca or Senegaw-Indians use it against the bite of the rattle-snake) The rattlesnake-root indkwort. Polygula senega of Linnærs :- floribus imberbibus spicatis, caule erecto herbaceo simplicissimo, folis lato lanceolutis. The root of this plant was formerly much esteemed as a specific against the poison of the rattle snake, and as an antiphlogistic in plenrisy, pneumonia, &c. but the knowledge we have of it is so weak, it is now very much laid aside. Its dose is

from ten to twenty grains; but when employed, it is generally used in the form of decoction, which, when prepared according to the formula of the Edinburgh Pharmacopæia, may be given every second or third hour.

Sengreen. See Sedum majus.

SENNA. (From senna, an Arabian word, signifying acute; so called from its sharp pointed leaves.) Sennu alexandrina. Senna italica. Folium orientale. or Egyptian cassia. Cussia senna of Linnæus:-foliis sejugis subovatis, petiolis eglandulatis. The leaves of senna, which are imported here from Alexandria for medicinal use, have a rather disagreeable smell, and a subacrid, bitterish, nauseous taste. They are in common use as a purgative. The formulæ given of the senna by the colleges, are those of infusion, a powder, a tincture, and an electuary. See Infusum senua, &c.

SENNA ALEXANDRINA. See Senna. SENNA ELECTUARIUM E. See Electuarium

SENNA ITALICA. See Senna.

SENNA PAUPERUM. Bastard senna, or milk-vetch.

SENNA SCORPIUM. The scorpion senna. SENNÆ EXTRACTUM. Extract of senna.

SENNÆ INFUSUM. SEE Infusum sennæ.

SENNA, INFUSUM TARTARIZATUM. Senna, coriander, and cream of tartar, infused in water.

SENSATION. Sensation, or feeling. is the consciousness of a change taking place in any part, from the contact of a foreign body with the extremities of our nerves. The seat of sensation is in the

pulp of the nerves. The impression produced on any organ by the action of an external body constitutes sensation. This sensation, transmitted by nerves to the brain, is perceived, that is, felt by the organ; the sensation then becomes perception; and this first modification implies, as must be evident, the existence of a central organ, to which impressions produced on the senses are conveyed. The cerebral fibres are acted on with greater or less force by the sensations propagated by all the senses influenced at the same time; and we could only acquire confused notions of all bodies that produce them, if one particular and stronger perception did not obliterate the others. and fix our attention. In this collective state of the mind on the same subject, the brain is weakly affected by several sensations which leave no trace behind. It is on this principle that, having read a book with great attention, we forget the different sensations produced by the paper and characters.

When a sensation is of short duration, that soon afterwards there does not remain any knowlege of having experienced hair, epidermis, nails, &c.; but the sensible it. In proportion as a sensation, or an idea, parts are the skin, eyes, tongue, ear, nose, which is only a sensation transformed or muscles, stomach, intestine, &cs. perceived by the cerebral organ, has produced in the fibres of this organ astronger or weaker impression, the remembrance of brum. it becomes more or less lively and permanent. Thus we have a reminiscence of it, that is, call to mind that we have already been affected in the same manner: a memory, or the act of recalling the object of the sensation with some of its attributes, as colour, volume, &c.

When the brain is easily excitable, and, tremities of the nerves. at the same time, accurately preserves SEPARATORIUM. (From separo, to sepa-impressions received, it possesses the pow-rate.) SEXUAL ACTION. Sexual functions. Those functions proper to each sex, by which the species is propagated, as the excretion of semen in men; menstruation, conception, the evolution of the fætus, parterition, &c. in women.

PLANTS. SEXUAL SYSTEM OF Linnæan system. The sexual system of plants was invented by the immortal Linnæus, professor of physic and botany at Upsal in Sweden. It is founded on the parts of fructification, viz. the stamens and pistils; these having been observed with more accuracy since the discovery of the uses for which nature has assigned them, a new set of principles have been derived from them, by means of which the distribution of plants has been brought to a greater precision, and rendered more conformable to true philosophy, in this system, than in any one of those which preceded it. The author does not pretend to call it a natural system, he gives it as artificial only, and modestly owns his inability to detect the order pursued by nature in her vegetable productions; but of this he seems confident, that no natural order can ever be framed without taking in the materials out of which he has raised his own; and urges the necessity of admitting artificial systems for convenience, till one truly natural shall appear. Linnæus has given us his Fragmenta methodi naturalis, in which he has made a distribution of plants under various orders, putting together in each such as appear to have a natural affinity to each other; this, after a long and fruitless search after the natural method, he gives as the result of his own speculation, for the assistance of such as may engage in the same pursuit.

Not able to form a system after the natural method, Linnaus was more fully convinced of the absolute necessity of adopting an artificial one. For the student to enter into the advantages this system maintains over all others, it is necessary that he be instructed in the science of and the species into varieties, where they botany, which will amply repay him for are worthy of note. his inquiry. The following is a short out-

line of the sexual system:

The parts of the fructification of a plant

1. The calyx, called also the empalement,

or flower-cup.

2. The corols, or foliation, which is the gaudy part of the flower, called vulgarly the leaves of the flower.

3. The stamens, or threads, called also the chives; these are considered as the male parts of the flower.

4. The pistil, or pointal, which is the female part. 5. The pericarp, or seed-vessel.

6. The seed.

7. The receptacle, or base, on which

these parts are seated.

The four first are properly parts of the flower, and the three last parts of the fruit. It is from the number, proportion, position, and other circumstances attending these parts of the fructification that the classes and orders, and the genera they contain, are to be characterised, according to the sexual system.

Such flowers as want the stamens, and

have the pistil, are termed female.

Those flowers which have the stamens, and want the pistils, are called male.

Flowers which have both stamens and pistils are said to be hermaphrodite.

Neuter flowers are such as have neither stamens nor pistils.

Hermaphrodite flowers are sometimes distinguished into male hermaphrodites and female hermaphrodites. This distinction takes place when, although the flower contains the parts belonging to each sex, one of them proves abortive or ineffectual; if the defect be in the stamina, it is a female hermaphrodite, if in the pistil, a male one.

Plants, in regard to sex, take also their denominations in the following man-

1. Hermaphrodite plants are such as bear flowers upon the same root that are all hermaphrodite.

2. Androgynous plants, are such as, upon the same root, bear both male and female flowers, distinct from each other, that is,

in separate flowers. 3. Male plants, such as bear male flowers

only upon the same root.

4. Female plants, such as bear female flowers only upon the same root.

5. Polygamous plants, such as, either on the same or on different roots, bear hermaphrodite flowers, and flowers of either or both sexes.

The first general division of the whole body of vegetables is, in the sexual system, divided into twenty-four classes; these again are subdivided into orders; the orders into genera, the genera into species;

Explanation of these terms.

As these terms in the Greek language, flowers must all be hermaphrodite in these from whence they are taken, are all exclasses; for should the female part be pressive of the principal circumstance that wanting, the plant would belong to some obtains in the class to which they are ap-other class, notwithstanding the number plied, the explanation of them will give of stamina may be such as would otherthe reader a good insight into the proper wise refer it to one of these. characters of the several classes, and the sexual distinctions on which they are armp, a husband.

husband, that is, a stanien.

Diandria; from dis, two, and avnp, a husband.

Triandria; from Tpus, three, and armp, a husband.

Tetrandria; from Teorapes, four, and avnp. a husband.

Pentandria; from werls, five, and arnp, a husband.

Hexandria; from &, six, and annp, a

Heptandria; from 1772, seven, and armp, a husband. Octandria; from outw, eight, and armp,

Enneandria; from errez, nine, and armp, a husband

Decundria; from sena, ten, and armp, a husband.

It is necessary to observe here, that the

Dodecundria; from Sasena, twelve, and

Notwithstanding the term implies that Monandria; from moros, one, and arng, a the flowers have twelve husbands, the class is not confined to this number, but includes all such hermaphrodite flowers as are furnished with any number of stamina, from twelve to nineteen inclusive. No flowers have yet been discovered that have eleven stamina, which is the reason no class has been allotted to that number.

Icosandria; from eixogi, twenty, and arne, a husband.

Here, again, the title is to be understood with considerable latitude; for though it means that the flowers have twenty stamens, yet the plants belonging to this class are rarely found with less, and they frequently have a greater number, and are therefore not to be known with certainty from the next class.

Polyandria; from woxus, many, and 2740, a husband.

phrodite plants whose flowers have more this title, it must be observed, that the stamens disunited than twenty.

Didynamia; from Sis, two, and Suvapies,

This term imports the power or superiority of two, and is applied to this class, because its flowers have four stamina, of ludes to this circumstance, that in this which there are two longer than the rest. class the male and female flowers are both This circumstance alone is sufficient to distinguish this from the fourth class, where the four stamens are equal.

Tetradynamia; from reovepes, four, and

Surauis, power.

This term implies the power or superiority of four, and accordingly there are in the flowers of this class six stamens, four of which are longer than the rest, which circumstance distinguishes them from those of the sixth class where they are equal.

Monadelphia; from moves, one, and adex-

φος, a brotherhood.

The word here compounded with the numerical term, signifies a brother. This relation is employed to express the union of the filaments of the stamen, which in this class do not stand separate, but join at the base, and form one substance, out of which they proceed as from a common mother, and the title, therefore, expresses a single brotherhood, meaning, that there is but one set of stamens so united, which distinguishes this class from the two following. The number of stamens, it is to be recollected, is not limited.

Diadelphia; from Sis, two, and asexpos,

a brotherhood

This term implies a double brotherhood, or two sets of stamens, united in the manner explained in the former class. number of stamens is not limited.

Polyadelphia; from woxus, many,

αθελφος, a brotherhood.

Many brotherhoods or sets of stamens is meant by this term.

Sungenesia; from our, together, and

ywers, generation.

This term implies congenegation, alluding to the circumstance of the stamens; in which, though the stamens stand separate, yet their anthers or tops, which are the parts more immediately subservient to generation, are united in a cylinder, and perform their office together.

Gynundria; from youn, a wife, and aunp, woman.

a husband.

This term alludes to the singular cir- woman. cumstance of this class, in the flowers of which the stamens grow upon the pistil; thirteen first classes, and the general exso that the male and female parts are united, and do not stand separate, as in other hermaphrodite flowers.

Monoecia; from moves, one, and omes, a

The word here compounded with the numerical term, signifies a house or habita- σπερμα, a seed.

This class comprehends those herma- tion. To understand the application of plants of this class are not hermaphrodite. but androgynous; the flowers that have the stamens wanting the pistil, and those that have the pistil wanting the stamen, so that monoecia signifying a single house, alfound on the same plant or house.

Dioecia; from Sis, two, and oings, a

This term signifies two houses, and is applied to this class, the plants of which are male and female, to express the circumstance of the male flowers being on one plant, and the female on another; the contrary of which is the case of the androgynous class Monoecia.

Polygamia; from woxus, many, and ya-

mos, nuptials.

This term implies plurality of marriages. This class produces, either upon the same or different plan's, hermaphrodite flowers, and also flowers of one sex only, be it male or female; or flowers of each sex; and the latter receiving impregnation from, or giving it to the hermaphrodites, as their sex happens to be the parts essential to generation in the hermaphrodite flowers, do not confine themselves to the corresponding parts within the same flower, but become of promiscuous use, which is the reason of giving this title.

Cryptogamia; from neumlos, concealed,

and yamos, nuptials.

This term means a concealment of marriages; the class consists, therefore, of such plants as either bear their flowers concealed within the fruit, or have them The so small as to be imperceptible.

Explanation of the titles of the orders.

Monogynia; from moves, one, and your, a woman, that is, a pistil.

Diagynia; from dis, two, and youn, a woman.

Trigynia; from Tpess, three, and youn, 2 woman.

Tetragynia; from reorapes, four, and yuvn, a woman.

Pentagynia; from wavle, five, and yuvn, a woman.

Hexagynia; from &, six, and yuvn, 2 woman.

Decagynia; from Sena, ten, and yuvn, 2

Polygynia, from woxus, many, and yuvn, 2

These are the titles that occur in the planation of one pistil, two pistils, &c. will be sufficient to make it appear how they are employed in the class.

The class didynamia contains the or-

Gymnospermia; from yumos, naked, and

Angiospermia; from alyos, a vessel, and σπερμα, a seed; which are distinguished by the seed being either naked, or en- system has been introduced, in order to closed in a pericarp or seed-vessel.

The two orders in the class Tetradynamia are founded on a distinction in the

pericarp.

Siliculosa; means a little siliqua.

Siliqua; which is a particular kind of title Materia Medica seed-vessel

To explain the orders contained in the elass Syngenesia, viz. Polygamia aqualis, Polygamia superfina, Polygamia frustranea, Polygumia necessaria, Polygumia segregata, Monogamia, it is necessary to explain what is meant by polygamy in flowers. It has been before observed, what is meant by for punch before the spirit is added. polygamous plants: but, in respect to flowers, the term is applied to a single flower only, for the flowers of this class being compound, a polygamy arises from the intercommunication of the several florets in one and the same flower. Now, the polygamy of flowers, in this sense of the word, al- jaw fords tour cases, which are the foundations of the four first orders of this class: equal gogu; from σιαλαγωγα, saliva, and αγω, polygamy, is when all the flowers are here to expel.) Those medicines are so called, maphrodite: superfluous polygamy, is when which excite an uncommon flow of saliva: males is a superfluity: frustraneous poly- parations of mercury. gamy, is when some of the florets are hermaphrodite, and others neuter; for, in this case, the addition of the neuters is of no assistance to the fructification: necessury polyzumy, is when some of the florets are male, and the rest female; for, in this case, there being no hermaphrodites, the polygamy arising from the composition of the florers of different sexes, is necessary to perfect the fructification; polygumia segreguta implies separation; the plants of this order having partial cups growing out of the common calyx which surround and divide the florets: the order Mouogiamia signifies a single marriage, and is opposed to the polygamy of the four other orders; for in this, although the anthers are united which is the essential character of the flowers of this class, the flower is simple, and not compounded of many florets, as in the other orders.

The tule of the other order to that of Trioccia, in the class Polygamia, have al-

ready been explained.

Telorcia; from Tests, three, and sixos, a house; because the polygamy is on three distinct plants, one producing male flowers, another female, and a third hermaphrodite or androgynous

The class Cryptogamia contains the or-

ders of

Flices, or ferns; Musei, or mosses;

Alga, or flags;

Fungi, or mushrooms.

This short explanation of the Linnaan convey a general idea to medical students of its nature, and also the meanings of the several terms.

The various medicinal plants will be found systematically arranged under the

Seudschutz water See Sedlitz water.

Sicchasta. (From ouxxos, weak, weary.) An impleasant lassitude and debility peculiar to women with child.

SICULA. (Dim. of sica, a short sword; so called from its dagger-like root.)

SICTEDON. (From TIXUGE, a cucumber.) A transverse fracture like a cucumber broken in two parts.

SICTORE (From TIRVOS, a cucumber or gourd; so named from its resemblance to

a gourd.) A cucurbit.

Sideratio. (From sidus, a planet, because it was thought to be produced by the influence of the planets.) An apoplexy; a blast: a slight erysipelas.

SIDERIUM. (From oidness, iron;) an herb so called from its supposed virtues in healing wounds made by iron instruments

SIGESBECKIA ORIENTALIS. The systematic name of a plant which is said to be useful in removing strangury, and in calculoos diseases, gout, and fluor albus.

SIGHT. See Seeing

SIGILLATA TERRA. Sealed earth; a species of bolar earth made into cakes.

SIGILLUM BEATE MARIE.

SIGILLUM HERMETICUM. An hermetic seal; mad by closing the end of a glass tube by melting it.

\* 5 C

SIGILLUM SALOMONIS. (Dim. of signum, a sign. It is called sigillum sulomonis, Solomon's seal, because it has upon its root the resemblance of an impression made by a seal.) Solomon's seal. Convolvulus polygonutum of Linnæus:—foliis alternis amplexicaulibus, caule ancipiti, pedunculis axillaribus subunifloris. The roots are applied externally as adstringents, and are administered internally as corroborants.

SIGMOID. (Sigmoides, from the Greek letter  $\Sigma$ , and sides, a likeness; resembling the Greek letter sigma.) Applied to the valves of the heart, and sometimes to the cartilages of the aspera arteria, or the semilunar apophysis of the bones.

SIGMOIDEA FLEXURA. The sigmoid flexure,

or turn of the colon.

SIGMOIDES PROCESSUS. Valves of the heart.

SIGNA CRITICA. Signs of the crisis of disease.

SIGNA DIAGNOSTICA. Diagnosis or distinguishing signs.

SILER MONTANUM. See Seseli.

SILER MONTANUM. Common hart-wort.

SILEX. (Selag, Heb.) Silex, or siliceous earth, is the principal constituent part of a very great number of the compound earths and stones forming the immense mass of the solid nucleus of the globe. It is the basis of almost all the scintillating stones, such as flint, rock crystal, quartz, agate, calcedony, jasper, The sand of rivers and of the seashore, chiefly consist of it. It is deposited in vegetable substances forming petrified wood, &c. It is likewise precipitated from certain springs in a stalactical form. It has been discovered in several waters in a state of solution, and is found in many plants, particularly grasses and equise-tums. Professor Davy has proved that it forms a part of the epidermis of these vegetables. It is never met with absolutely pure in nature.

Properties.—Silex, when perfectly pure, exists in the form of a white powder. It is insipid and inodorous. It is rough to the touch, cuts glass, and scratches or wears away metals. Its specific gravity is about 2.66. It is unalterable by the simple combustible bodies. When mixed with water it does not form a collesive mass. Its moleculae when diffused in water are precipitated with the utmost facility. It is not acted on by any acid, except the fluoric. When in a state of extreme division it is soluble in alkalis; fused with them it forms glass. It melts with the phosphoric and boracic acids. It is unchangeable in the air, and unalterable by oxygen and the rest of the gazeous fluids. It has been considered as insoluble in water, but it appears when in a state of

extreme division to be soluble in a minute quality.

Method of obtaining silex -Silex may be obtained, tolerably pure, from flints, by the following process: procure some common gun-flinis; expose them in a crucible to a red heat, and then plunge them into cold water; by this treatment they will become brittle, and easily reducible to powder. Mix them, when pulverized, with three or four times their weight of carbonate of potash, and let the mixture be fused, in a dull red heat, in a silver crucible. shall thus obtain a compound of alkali and silex, called siliceous potash. Dissolve this compound in water, filter the solution, and add to it diluted sulphuric or muriatic acid. An immediate precipitation now ensues, and as long as this continues, add fresh portions of acid. Let the precipitate subside; pour off the fluid that floats above it; and wash the precipitate with hot water till it comes off tasteless. This powder when dry is silex.

In this process the acid added to the solution of flint unites to the potash, and forms sulphate or muriate of potash; the siliceous earth is therefore precipitated.

It is necessary to add an excess of acid, in order that all the foreign earths which

are present may be separated.

If the solution of flints be diluted with a great quantity of water, as for instance, in the proportion of 24 parts to one, and in this state an acid be poured upon it, no perceptible precipitation will ensue; the silex continues suspended in the fluid, and is invisible on account of its transparency; but it may be made to appear by evaporating part of the water.

The solution of flint, on account of its affinity with the carbonic acid is also in course of time decomposed by mere con-

tact with air.

Another method of obtaining silex exceedingly pure is to separate it from fluoric acid.

SILICA. (From silex.) Siliceous earth. See Silex.

SILIGO. ZIAIYVIS. Fine wheat or rye.

SILIQUA. (From silo, a nose turned up, a hooked nose.) A pod or receptable for seed, consisting of two valves, and in which the seeds are fixed alternately to each suture. Also some plants which bear pods.

SILIQUA DULCIS. Sweet-pod. The fruit so called is the produce of the Ceratonia siliqua of Linnæus. They are about four inches in length, and as thick as one's finger, compressed and unequal, and mostly bent; they contain a sweet brown pulp, which is given in form of decoction, as a pectoral in asthmatic complaints and coughs.

SILIQUA HIRSUTA. The cowage is some-

times so called. See Dolichos.

SILIQUASTRUM. (From siliqua, a pod;

named from its pods.) Judas-tree. The pyrometer. by Pliny. See Piper indicum.

its juice is alexipharmic.

SKIN. carefully dissected off and separated from almost an inch long; the cuticle, or rete all adventitious matter in a middle-sized mucosum, or a membrane very similar, man, it weighs about four pounds and a having the same properties with these, aphalf.

membrane, is in reality laminated, consiste surface of the lungs, esophagus, stomach, ing of several subdivisions; the outermost and intestinal tube. In most of the last-

afford the yellow saunders. See Santalum ticle; the second has no English name, is known only to anatomists, and is called rete mucosum; after these two are removed we come to, as is commonly thought, the surface of the skin itself.

When a blister has been applied to the skin of a Negro, if it has not been very stimulating, in twelve hours after a thin transparent greyish membrane is raised, under which we find a fluid. This membrane is the cuticle or scarf skin. When this, with the fluid, is removed, the surface under them appears black; but if the blister had been very stimulating, another membrane, in which this black colour resides, would also have been raised with the cuticle; this is rete mucosum, which is itself double, consisting of another grey transparent membrane, and of a black web, very much resembling the nigrum pigmentum of the eye. When this membrane is removed, the surface of the true skin (as has hitherto been believed) comes in view, and is white, like that of a European. The rete mucosum gives the colour to the skin; is black in the Negro; white, brown, or yellowish, in the European. The reason why this membrane is black in the Negro is, perhaps, that his body may be better able to defend itself against the sun's rays, and that the heat may be prevented from penetrating. The intention of a similar membrane behind the retina in the eye, appears to be not only that of absorbing the superfluous rays of light; but, like the amalgam behind the looking glass, it may enable the retina to reflect the rays, in order to perfect vision. It is not very improbable that some such purpose, as enabling the cuticle to reflect the sun's rays in those warm climates, where the inhabitants originally go naked, may be the intention of nature, in giving them the black membranc. Perhaps too, the circumstance of the countenance's becoming brown, when exposed to the sun's rays in summer, in our own climate, may be a process of nature to defend herself against the access of external heat into the body.

Both cuticle and rete nucosum send innumerable processes into the pores of the A skele- truc skin; the process of the rete mucosum ton is so termed in opposition to an artifi- is always within that of the cuticle, and in cial one, when the bones are retained in contact with the sides of the pore, as their proper places by means of their na- formed by the true skin. These processes are remarkable in the cuticle and rete mu-(Asgue. Pellis. Cutis.) When cosum of the elephant, some of them are pears to be also continued into the inside The skin, though apparently a simple of the mouth, over the tongue, internal lamen is termed with us scarf skin, or cu- named parts, the cuticle, however, forms

sheaths for villi, and not processes which line pores. On viewing the surface of the skin, even with the naked eye, we find it porous; more so in some places than in others; and the pores are also larger in some parts then others. These pores are ducts of sebaceous glands, and serve not only to transmit hairs, but, it is supposed, the greatest part of the perspirable matter itself. Absorption on the skin also, in all probability, begins on the sides of these pores. They are particularly remarkable about the mouth, nose, palms of the hands, soles of the feet, on the external ear, scalp, mons veneris, and around the nipple in women.

The skin itself was given to man not only for feeling, in a general sense, but for perspiration, absorption, and particularly for touch, in which he excels all other animals, and which resides, principally in the tips of the fingers He was intended for examining, reasoning, forming a judgment, and acting accordingly; he was fitted by this sense to examine accurately the properties of surrounding bodies, not capable of being examined by his other senses. This, among other reasons, was one why he was made erect, that the points of his fingers should not be made callous, or less sensible, by walking on

The skin of human bodies is always of a white colour, in the dead body, let the colour of the rete mucosum be what it may, it is extremely full of pores, and extremely vascular; a child in full vigour comes into the world, from this circumstance, scarlet; it is endowed with intense sensibility: almost all the pain, in the different operations of surgery, is past when we have divided the skin. Some parts of the skin have more feeling than others; the lips, for example, as Haller says "ad busia destinata." The glans clytoridis, and the glans penis, with a similar intention; there. though the nerves are not so large as in some other parts, they are longer, more numerous, and endowed with more exquisite feeling; but where the common offices of life merely are intended, the marks of superior feeling or touch, in the skin, are the projections, above the common surface, of those packets of arteries, veins, absorbents, called villi; the nerves are there not only also longer, but larger, as in the points of the fingers and toes.

We are not certain that the skin is muscular, but it has properties very like those of muscle, it contracts, relaxes, and even vibra'es, in some places, on certain occasions. It is extremely distensible, the skin of the perinaum has stretched in labour from a quarter of an inch to six inches. It is also extremely elastic, and instantly after labour has returned again to the ori- branches of the internal maxillary, above,

ginal quarter of an inch; it is thickest on those parts intended by nature to bear weight or pressure; of course it is thickest on the back, on the soles of the feet, and palms of the hands. It is thinner on the fore part of the body, on the insides of the arms and legs, and where its surfaces touch opposite surfaces. It is extremely thin on the lips, and allows the colour of the blood to shine through it. It is also extremely thin on the glans penis in men, glane clutoridis in women, and on the inside of the labia pudendi. Skin dried and dressed is extremely strong and durable, and therefore employed in making harness for horses, clothing for men, and a variety of other

Skin, scarf See Cuticle and Skin.

Skink. See Scincus.

SKULL. The skull or cranium is that boney hox which contains the brain: it forms the foreliead, and every part of the head except the face. It consists of eight bones, namely one os frontis, one os occipitis, one os sphænoides, one os æthemoideum, two ossa temporalia, and two ossa parietalia.

Slaters. See Millepedes.

SLEEP. Somnus. That state of the body in which the internal and external senses and voluntary motions are not exercised. The end and design of sleep is both to renew, during the silence and darkness of the night, the vital energy which has been exhausted through the day, and to assist nutrition.

Sloe. See Prunus sylvestris. Smallage. See Apium. Small-pox See Variola.

SMELLING. The sense of smelling is performed by means of a soft, pulpy, vascular, papillons, porous membrane, which lines the whole internal cavity of the nostrils, and is thicker upon the septum, and principal cavity of the nose, but thinner in the sinuses. It is plentifully supplied with very soft nerves, the middle one of which descend from the first pair, through the holes of the os cribosum to the septum narium; but in such a manner, that it is very difficult to trace them to their extremities and into the septum. Other lateral nerves come from the second branch of the fifth pair and its branches, from that which crosses the pierygoid ca-nal, and from another which descends through the canals of the palate; and in the maxillary sinus from the infra orbital branch, from the dental branch, and from the anterior nerve of the palate. terior part of the septum has a twig from the oplithalmic of the first branch of the fifth pair.

The nostrils are supplied with very numerous arteries; from the three nasal both from the ethmoidal branches, and the frontal and nasal branches, with lateral arteries from the smaller ophthalmic branch of the internal carotid, and from branches of the palatine artery, and in the sinuses from the infra-orbital, and from the superior dental one. These arteries have the property of exuding blood easily, and in great quantity, without any lesion of eonsequence. The correspondent veins form a very large plexus upon the external pterygoid muscle; then communicate with the sinuses of the dura mater; and, lastly, meet in the external branch of the internal jugular. The arteries supply nourishment, warmth, and mueus.

The air, filled with the very subtile, invisible, pungent, oily, saline, and volatile effluvia, which exhale from almost every known body, being received into the nostrils, by the action of respiration, and by a peculiar effort for drawing the air into them, carries these particles to the nerves, widely naked, and constantly soft. By these there is excited in the nerves a kind of sensation which we call smell, by which we distinguish the several kinds of oils and salts, in a manner somewhat indistinct, difficultly reducible to classes, difficultly ciently for our purposes. This sense in- nostrils. forms us of unwholesome putridity, of excessive acrimony, and of the bland and useful nature of substances. And as salt, united with oil, is an object of taste, and as oils, combined with salts, constitute odours, the affinity of the two senses, which is necessary to derive utility from either, is apparent. But volatile particles chiefly are distinguished by smell, and fixed ones by the taste; perhaps because the thick mucous cutiele, spread over the tongue, intercepts the action of the more subtile salts, which easily affect the softer and less covered nerves of the nostrils. in the mineral kingdom, united with sulthis respect.

short continuance; because particles in a countries, from which it is extracted by very minute state are applied to naked running water. Thus it is found after the nerves, in the immediate vicinity of the spontaneous evaporation of the water, mixbrain. Hence the deleterious and refresh- ed with sand in the bottom of lakes in Huning actions of odonrs, by which people gary; in the neghbo thood of Bilin in Boare resuscitated from faintings, and even hemia; and in Switzerland. It occurs also from drowning. Hence the violent sucez- in China, and near Tripole in Syria, Egypt, ing, excited by acrid particles, the evacu- Persia, and India. Socotorine aloes. An epithet of the best aloes which are brought from Socotria. See Alloes.

SODA. (An Arabian word.) The name now generalty given by chemists and physicians to the mineral alkali.

It is obtained from several sources, but principally from plants growing on the sea coast. See Natron and Barilla. It occurs We are ignorant of the reasons why some phuric, muriatic, and boracic acids; it is smells please, and others displease; per- also found in large quantities in Egypt, haps eustom may have some influence in combined with carbonic acid. It appears to be deposited in large impure masses, The action of smells is strong, but of under the surface of the earth, in various

ses on the borders of the Baltic. In this country we burn the various species of fuci; and in France they burn the chenopodium maritimum.

The alkali thus procured is more or less pure according to the nature of the particular plant from which it is obtained. The greatest part however is a subcarbonate of

In order to obtain it in a state of purity, the carbonate of soda must be treated, like potash of commerce, with lime and ardent

cularly from potash by the following pro- of perties:—In the fire it is rather more fusible. When exposed to the contact of the air it attracts water and carbonic acid, but it does not liquify like potash, it merely acquires a pasty consistence, and at last crumbles into powder. It is not altered by light. It attracts sulphur and sulphurated hydrogen more feebly. It adheres less strongly to the acids. It fuses and dissolves alumine more easily. All its other properties, its volatilization by a very high degree of heat, its acrid causticity, its solubility, its combinations with sulphur, &c. resemble those of potash,

Mr. Davy, having discovered the composition of potassa, submitted soda likewise to the same modes of analysis, and discovered that it too contains a substance of very singular properties, analagous to the base of potassa, though still essentially different from it, and that this base com-

bined with oxygen forms soda. When soda was submitted to the Galvamic action, in the mode already described with regard to potassa, the results were similar, globules of a metallic appearance were produced at the negative surface, which often burnt at the moment of their formation, and sometimes exploded with violence, separating into smaller globules which darted through the air in a state of vivid combustion. When these were produced an aëriform fluid was disengaged at the positive surface, which proved to be pure oxygen. The reproduction of soda from this substance was similar to that of potassa from the base of the alkali. When the base of soda was exposed to the air, a crust of alkali formed on its surface, and oxygen was absorbed. When heated, confined in a portion of oxygen gas, a rapid combustion with a brilliant white flame took place, and soda was produced in the state of a solid white mass. The theory of the decomposition of soda is the same with that of potassa. The combustitrified surfaces; and the oxygen follows the contrary order. Hence their separation

and evolution.

From the results of the combustion of the base of soda in oxygen gas, Mr. Davy inferred that one hundred parts of soda consist of eighty of base and twenty of oxygen. From the results of its oxidation by the decomposition of water, the proportions were estimated to be seventy-seven of base and twenty-three of oxygen. The mean proportions of these two modes are 78.5, and 21.5. The base of soda therefore combines with rather a larger proportion of oxygen than the base of potassa.

To the base of soda Mr. Davy from its Properties of Soda. - Soda differs parti- analogy to the metals has given the name

## SODIUM.

The following are its properties:-

Sodium is white, opaque, and, when examined under a film of naphtha, has the lustre and general appearance of silver. It is exceedingly malleable, and is much softer than any of the common metallic substances. When pressed upon by a platina blade, with a small force, it spreads into thin leaves, and a globule of the onetenth or one-twelfth of an inch in diameter is easily spread over a surface of a quarter of an inch, and this property does not diminish when it is cooled to 32° Fahren-

It conducts electricity and heat in a similar manner to the basis of potassa; and small particles of it inflame by the Galvanic spark, and burn with bright explosions.

Its specific gravity is less than that of water. It swims in oil of sassafras of 1.096 water being one, and sinks in naphtha of specific gravity 861 By mixing together oil of sassafras and naphtha, until a fluid was formed in which the globule of sodium remained at rest above or below, Mr. Davy found its specific gravity to be to that of water nearly as nine to ten, or more accurately as 9348 to 1.

Sodium has a much higher point of fusion than potassim, its parts begin to lose their cohesion at about 120° Fahrenheit, and it is perfectly fluid at about 180°, so that it readily fuses under boiling naphtha, it is also less volatile, it remains fixed in a state of ignition at the point of fusion of plate glass.

When sodium is exposed to the atmosphere it immediately tarnishes, and by degrees becomes covered with a white crust, which deliquesces much more slowly than the substance that forms on the basis of potassa. This crust is pure soda.

The basis of soda combines with oxygen slowly without any luminous appearance, at common temperatures, and, when heated, ble base, like other combustible substant this combination becomes much more ruces, is repelled by positively electrified pid, but no light is emitted until it has acsurfaces, and attracted by negatively elec- quired a temperature nearly that of ignition. The flame that it produces in oxygen gas is white, and it sends forth bright sparks, occasioning a very beautiful effect;

colour of that produced during the com- derable degree of heat. It makes an albustion of charcoal, but much brighter.

violent effervescence with a loud hissing noise, it combines with the oxygen of the water to form soda, which is dissolved, and its hydrogen is disengaged. In this operation there is no luminous appearance; of mercury and sodium seems to form tribut when it is thrown into hot water, the decomposition is more violent, and in this case a few scintillations are observed at the triple compound of a dark grey colour. surface of the fluid, owing to small particles of the base, which are thrown out of of a combination of acetous acid with the the water sufficiently heated to burn in passing through the atmosphere. when a globule is brought in contact with a small particle of water, or with moistened paper, the heat produced (there being no medium to carry it off rapidly,) is usually sufficient for the ascension of the sodium. carbonas.

The base of soda, when thrown upon the strong acids, acts upon them with great tron, Barilla and Soda. energy. When nitrous acid is employed, a vivid inflammation is produced: with muriatic and sulphuric acid there is much leat generated, but no light. When plunged soda. Alkali minerale phosphoratum ed beneath the surface of the acids, it is rapidly oxigenated; soda is produced and

combines with the acid.

Sodium, in its degrees of oxidation, has precisely similar habits with the base of potassa. When it is fused with dry sodain certain quantities, there is a division of scrophula, bronchecele, rachitis, and gout, oxygen between the alkali and the base, and a deep brown fluid is produced, which becomes a dark grey solid on cooling, and which attracts oxygen from the air, or which decomposes water, and becomes subcarbonus exsicenta.

The same body is often formed in the analytic processes of decomposition, and it is generated when the basis of soda is fuscel in tubes of the purest plate glass.

Sodium, when heated with hydrogen gas, does not, like potassium, appear to be dis- ounces; supertartrate of potash, powdersolved, and as no luminous appearance attends the oxidation of it in cold water, it Dissolve the supercarbonate of soda in the docs not appear to be capable of combining even with nascent hydrogen.

There is scarcely any difference in the visible phenomena of the agencies of the basis of soda, and that of potassa on sul-

phur, phosphorus, and the metals.

It combines with sulphur in close vessels filled with the vapour of naphtha with great vividness, with light, heat, and often with explosion from the vaporization of a portion of sulphur, and the disengagement of and it has been judged by the London Colsulphuretted hydrogen gas. The sulphu- lege more convenient to express this differretted base of sulphur is of a deep grey ence by the adjective tartarizata, than to colour. The phosphuret has the appear-introduce the three words necessary to its ance of lead, and forms phosphate of soda description. It possesses mildly cathartic, by exposure to the air, or by combustion, diuretic, and deobstruent virtues, and is

Sodium combines with the metals; in the administered in doses from one drachm to quantity of one-fortieth, it renders mercury an ounce, as a cathartic, and in the dose of a fixed solid of the colour of silver, and twenty to thirty grains in abdominal phys-

in common air it burns with light of the the combination is attended with a consiloy with tin, without changing its colour, When thrown upon water it produces a and it acts upon gold and lead when heated. In its state of alloy it is soon converted into soda by exposure to air, or by the action of water, which it decomposes with the evolution of hydrogen. The amalgam ple compounds with other metals. It likewise combines with sulphur, and forms a

SODA ACETATA. A neutral salt formed mineral alkali Its virtues are similar to

of Bergman. This preparation is a phosphat of soda, and therefore called phosphas sode in the new chemical nomenclature. It is cathartic in the dose of half an ounce to an ounce; dissolved in gruel it is not unpleasant, and is said to be useful, in

in small doses.

Soda, subcarbonate of. See Sodæ subcarbonas.

Soda, subcarbonate of, dried See Sode Soda, sulphate of. See Soda sulphas.

SODA TARTARIZATA. Tartarized

soda, formerly known by the names of sal rupellensis, sal polychrestum Seignetti, and lately by that of natron tartarizatum. "Take of subcarbonate of soda twenty cd, two pounds; boiling water ten pints." water, and add gradually the supertartrate of potash; filter the solution through paper, and evaporate it until a pellicle forms upon the surface; then set it by that crystals may form. Having poured away the water, dry these crystals upon bibulous paper. This salt consists of tartaric acids, soda, and potash, the soda only combining with the superabundant acid of the super salt; it is therefore a triple salt.

5 D

conia, and torpidity of the kidneys. See paper. It possesses cathartic and diuretic Seignet e's salt.

SODÆ BORAS. Borate ol' soda. See Borux.

SODÆ CARBONAS. Carbonate of "Take of subcarbonate of soda, a pound; subcarbonate of ammonia, three ounces; distilled water, a pint." Having previously dissolved the soda in water, add the ammonia, then by means of a sandbath apply a heat of 180° for three hours, or until the ammonia be driven off. Lastly, set the solution by to chrystallize. The remaining solution may be evaporated and set by in the same manner that crystals may aga n form.

SODÆ MURIAS. See Murias sodæ. SODE SUBCARBONAS. Subcarbonate of soda, formerly called natron praparatum and salsoda. "Take of impure soda, powdered, a pound; boiling distilled water, a gallon." Boil the soda in the water for half an hour, and strain the solution; let the solution evaporate to two pints, and be set by, that crystals may form. Throw away the remaining solution. This salt consists of soda saturated with carbonic acid, and is therefore called soda subcarbonas. It is given in doses of from ten grains to half a drachm as an attenuant and antacid; and, joined with bark and aromatics, it is highly praised by some in is sometimes so termed. See Dulcamara. the cure of scrophula. It is likewise a Solanum melongena. The systematic powerful solvent of mucus, a deobstruent and diuretic, and an antidote against oxyd of arsenic and the corrosive sublimate. of the garden nightshade. The other diseases in which it is administered are those arising from an abundance of mucus in the primæ viæ; calculous complaints, gout, some affections of the skin, rickets, tinea capitis, crusta lactea, and worms. Externally it is recommend-

SODÆ SUBCARBONAS EXSICCATA. Dried subcarbonate of soda. "Take of subcarbonate of soda, a pound." Apply a gentle heat to the soda in a clean iron vessel, until it becomes perfectly dry, and constantly stir it with an iron rod. Lastly, reduce it into powder. Its virtues are similar to those of the subcarbonate.

ed by some in the form of lotion, to be ap-

plied to scrophulous ulcers.

SODÆ SULPHAS. Sulphate of sodæ, commonly known by the name of natron vitriolatum, and formerly by sal catharticus Glauberi, "Take of the salt which remains after the distillation of muriatic acid, two pounds. Boiling distilled water, two pounds and a half." Dissolve the salt in water, then add gradually as much subcarbonate of soda as may be required to saturate the acid; boil the solution away until a pellicle forms upon the surface, and, after having strained it, set it by that crystals may form Having poured away the water, dry these crystals upon bibulous vessels.

qualities, and is in high esteem as a mild Soda, tartarized. See Sodo tertarizata, cathartic. It is found in the mineral king. dom formed by nature, but that which is used medicinally is prepared by art dose is from one drachm o one ounce.

SOL. The sun. Gold was so called by

the older chemists.

Solamen. (From solor, to comfort.) Anise-seed is named solamen intestinorum, from the comfort it affords in disorders of the intestines.

(From solanum, night-SOLANOIDES. shade, and sidos, likeness.) Bastard night. shade.

SOLANUM. (From solor, to comfort, because it gives ease by its stupifying qualities.) 1 The name of a genus of plants in the Linnæan system. Class, Pentan-dria Order, Monogynia. Nightshade

2. The pharmacopæial name of the solanum nigrum of Linnæus; its virtues are very nearly allied to those of the belladon-

na, which consult.

SOLANUM DULCAMARA. The systematic name of the bitter sweet. See Dulcamara.

The thorn-apple SOLANUM FEETIDUM. plant is sometimes so called. See Stramo.

SOLANUM LETHALE. See Atropha belladonna.

SOLANUM LIGNOSUM The bitter sweet

name of the mad apple plant. See Mad apple. SOLANUM NIGRUM. The systematic name See Sola-

The systematic SOLANUM SANCTUM. name of the Palestine nightshade. fruit of this plant is globular, and in Egypt much eaten by the inhabitants.

SOLANUM TUBEROSUM. See Potatoe.
SOLANUM VESICARIUM. The winter cherry plant is so called by Caspar Baulin.

See Alkekengi.

SOLDANELLA. (A solidando, from its uses in healing fresh wounds.) The sea convolvulus. See Brassica marina.

Solen. (Swarr.) A tube or channel. A cradle for a broken limb.

Solenarium. (Dim of σωλην, a tube.) A catheter.

SOLEUS. (From solea, a sole, from its shape being like the sole fish.) See Gastrocnemius internus.

(From solido, to make SOLIDAGO. firm; so called from its uses of consolidating wounds.) The name of a genus of plants in the Linnæan system. Class, Syngenesia. Order, Polygamia superflua. The herb comfrey

Solidago VIRGAUREA. The systematic name of the golden rod. See Virga aurea.

SOLIDS, in anatomy, are the bones, ligaments, membranes, muscles, nerves, and

Source (From solus, alone; so called because it infests the body singly) The tape-worm.

Solomon's SEAL. The convallaria polygo-Useful as an ontward application for broises; dried and powdered is said to be antidysenteric, and if beaten into a conserve with sugar whilst it is green, is recommended in leucorrhea.

Solskarium (From sol, the sun, and sequer, to follow, so called because it turns its flowers towards the sun.) Marygold or

turnsole.

SOLVENT Sec Menstruum,

SOLUTION. An intimate commixture of soud bodies with fluids, into one seemingly homogeneous liquor. The dissolving fluid is called a mensirium or solvent,

SOLUTIVA. (From solvo, to loosen.) Laxative medicines. Gentle purgatives.

Somnambulism. Sleep-walking. Sce Oneirodynia.

Sounifena. (From somuns, sleep, and fero, to bring.) Opiates; medicines which induce sleep.

Sonchires. (From σογχος, the sowthistle; so named from its resemblance to the souchus.) The herb hawkweed

SONUHUS. (Παρα το σωον χεειν, from its wholesome juice.) The name of a genus of plants in the Linnxan system. Class, Syngenesia. Order, The sowthistle. All the species of sonchus abound with a milky juice, which is very bitter, and said to possess duretic virtues. sonchus oleraceus of Lannæus is sometimes employed with that intention. Boiled it may be eaten as a substitute for cabbage.

The systematic Sonchus oleraceus, name of the sow-thistle. See Sonchus.

Soor, Fuligo. A volatile matter, arising from coals, wood, and other fuel, along with the smoke. It is used as a material for making muriate of ammonia. At no very remote period our dispensatories contained directions for a tineture of soot; the most material ingredient of which, however, was assafœtida.

Sornia. (From copoc, wisc; so named from its great virtues in stopping fluxes.)

Flix-weed or flux-weed.

SOPHIA CHIRURGORUM. This plant, Sisymbrium sophia of Linnaus, is now almost banished from practice. It was formerly in high estimation in the cure of wounds. It has been given internally in hysterical affections and uterine hæmorrhages, and the seeds are said to be efficacious in destroying intestinal worms

SOPHISTICATION. A term employed in pharmacy, to signify the counterfeiting or adulterating any medicine. This practice unhappily obtains with most dealers in drugs, &c.; and the cheat is carried on so artificially by many as to prevent a discovery even by persons of the most discerning faculties.

Sophonisteres. (From σοφεονίζω, to become wise; so called bec use they do not appear till after puberty.) The last of the grinding teeth.

Sopnora HEPTAPHYLLA. The systematic name of the shrub whose root and seeds are sometimes called anticholerica: they are both intensely bitter, and said to be

useful in cholcra, colic, and dysury. Sopientia. (From sopio, to make sleep ) Opiates.

SOPOR Profound sleep.

SOPORIFEROUS. (Soporifera medicamenta. From sopor, sleep, and fero, to bear.) A term given to those medieines which induce sleep. See Anodynes.

Sona. (Arab.) The nettle-rash.

SORBASTRELLA. (From sorbeo, to suck up, because it stops hamorrhages.) The herb

SORBUS. (From sorbeo, to suck up; because its fruit stops fluxes.) The name of a genus of plants in the Linnaan system. Class, Icosandria. Order, Trigynia. The service-tree

Source Aucuparta. The wild service. tree. The berries of this plant are adstringent, and, it is said, have been found serviceable in allaying the pain of calculous

affections in the kidneys.

SORDES. When the matter discharged from ulcers is rather viscid or glutinous, it is thus named. This matter is frequently of a brownish red colour, somewhat resembling the grounds of coffee, or grumous blood mixed with water: Sordes, Sanies, and Ichor, are all of them much more fetid than purulent matter, and none of them are altogether free from acrimony; but that which is generally termed Ichor is by much the most acrid of them, being frequently so sharp and corrosive as to destroy large quantities of the neighbouring parts.

Sore-BAY. A disease which Dr. Mosely considers as a true cancer, commencing with an ulcer. It is endemic at the Bay of

Honduras.

Sove-throat. See Cynanche. Sorrel, common. See Acetosa. Sorrel, French. See Rumex scutatus. Sorrel, roundleaved. See Rumex scuta-

Sorrel wood. See Lujula.

SOUND. An instrument which surgeons introduce through the urethra into the bladder, to discover whether there is a stone in this viscus or not.

Sour dock. See Acetosa

Southernwood. See Abrotanum.

Sow-bread. See Arthonita. Sow-breed See Cyclamen.

SPA WATER. This mineral water appears to be a very strongly acidulous chalybeate, containing more iron and carbonic acid than any other mineral spring What applies to the use of chalybeates will anply to this water.

Spain, pellitory of. See Pyrethrum. Spanish fly. See Cantharides. Spanish liquorice. See Glycirhiza.

SPARGANOSIS. (From onagyaw, to swell.)

A milk abcess

SPARTIUM. The name of a genus of eye fixed. plants in the Linnæan system. Class, Diadelphia. Order, Decandria.

SPARTIUM SCOPARIUM. The systematic name of the common broom. See Ge-

SPASM. (Spasmus, from oraw, to draw.) A spasm or convulsion An involuntary contraction of the muscular fibres, or that state of the contraction of muscles which is not spontaneously disposed to alternate When the contractions with relaxation. alternate with relaxation, which are frequently and preternaturally repeated, they are called convulsions. Spasms are distinguished by authors into clonic and tonic spasms. In clonic spasms, which are the true convulsions, the contractions and relaxations are alternate, as in epilepsy; but in affections of the lungs, prima via, kidin tonic spasms the member remains rigid, as in locked jaw. See Convulsion, Tonic spasm, and Teranus.

SPASMI. Spasmodic diseases. third order of the class neuroses of Cullen; characterised by a morbid contraction or cle and ovary, as the spermatic artery,

motion of muscular fibres.

Spasmodic colic. See Colica.

a spasm, and holos, a discourse.) A trea-

tise on convulsions.

SPASMUS CYNICUS. The spasmus cynicus, or sardonic grin, is a convulsive affection of the muscles of the face and lips on both sides, which involuntarily forces the muscles of those parts into a species of grinning distortion. If one side only be affected, the disorder is nominated tortura When the masseter, buccinator, temporal, nasal, and labial muscles, are involuntarily excited to action, or contorted by contraction or relaxation, they form a species of malignant sneer. It sometimes arises from eating hemlock, or other acrid poisons, or succeeds to an apoplectic and sides, a likeness; because it is fixed in stroke.

инан, a probe.) An edged probe.

SPATULA. (Dim. of spatha, a broad instrument.) An instrument for spreading called from its wedge-like situation amidst salve. Also a name of the herb spurge- the other bones of the head, is of a more wort, from its broad leaves.

Spearmint See Mentha sativa. Spearwort, water. See Flammula.

SPECIFIC. A remedy that has an infallible efficacy in the cure of disorders. The any thing it resembles more. existence of such remedies is doubted

Specialum. (Prom specio, to examine.)

SPECULUM ANI. An instrument for distending the anus whilst an operation is performed upon the parts within.

ment to assist in any manual operation be-

longing to the womb.

SPECULUM OCULI. (Speculum, from specio, to view.) An instrument used by oculists to keep the eyelids open and the

An instrument to SPECULUM ORIS.

force open the mouth.

SPECULUM VENERIS. See Millefolium.

Speech See Voice.

Speedwell, female. See Elatine. Speedwell, male. See Veronica. Speedwell, mountain See Veronica.

SPERMA-CETI. (From omspua, seed, a oneipw, to sow, and cete or cetus, the whale.) Cetaceum. An oily, concrete, crystalline, semi-transparent matter, obtained from the cavity of the cranium of several species of whales, but principally from the Physeter maero cephalus, or spermaceti whale It was formerly very highly esteemed, and many virtues were attributed to it; but it is now chiefly employed neys, &c. as a softening remedy, mixed with mucilages It is also employed by surgeons as an emollient in form of cerates, ointments, &c.

SPERMATICA. Belonging to the testi-

chord and veins.

SPERMATOCELE. (From σπερματο. Spasmology. (Spasmologia, from σπασμος, κηλη, from σπερμα, seed, and κηλη, a tumour.) Epididymis distensa. A swelling of the testicle or epididymis from an accumulation of semen. It is known by a swelling of those organs, pain extending to the loins without inflammation.

SPERMATO PŒETICA. (From σπερμα, and ποιεω, to make.) Medicines which increase

the generation of seed.

(From σφακελιζω, SPHACELISMUS. to gangrene.) A gangrene. Also a phre-

SPHACELUS. (From equan, to destroy.) A mortification of any part. See

Gangrene.

SPHÆNOIDES OS. (From ophy, a wedge, the cranium like a wedge.) Os cuneiforme, SPATHOMELE. (From onadh, a sword, and os multiforme. Os azygos. Papillare os. Basilare os. Os polymorphos. Pierygoid bone. The os splienoides, or coneiforme, as it is irregular figure than any other bone. It has been compared to a bat with its wings extended. This resemblance is but faint, but it would be difficult perhaps to find

We distinguish in this bone its body or middle part, and its wings or sides, which are much more extensive than its

body.

Each of its wings or lateral processes is divided into two parts. Of these the up-SPECULUM MATRICIS. An instru- permost and most considerable portion,

757 SPII

helping to form the deepest part of the The two latter are frequently united into ten poral fossa on each side, is called the one. temporal process. The other portion makes a part of the orbit, and is therefore named noides, immediately under the sella turthe orbitar process. The back part of each cica, we find two cavities, separated by a wing, from its running out sharp to meet thin bony lamella. These are the sphethe os petrosum, has been called the spi- noidal sinuses. They are lined with the nous process; and the two processes, which pituitary membrane, and, like the frontal stand out almost perpendicular to the ba- sinuses, separate a mucus which passes sis of the scull, have been named pterygoid into the nostrils. In some subjects there or aliform processes, though they may be is only one cavity; in others, though more said rather to resemble the legs than the rarely, we find three. wings of the bat. Each of these processes

In infants the os sphenoides is composed
bas wo plates and a middle fossa facing of three pieces, one of which forms the
backwards; of these plates the external body of the bone and its pterygoid proone is the broadest, and the internal one cesses, and the other two its lateral prothe longest. SPINA ARABICA. The chardon or Arabian thistle.

SPINA BIFIDA. Hydrops medullæ spinalis. Hydrocele spinalis. Hydrorachitis spinosa. A tumour upon the spine of newborn children immediately about the lower vertebræ of the loins, and upper parts of the sacrum; at first, it is of a dark blue colour; but in proportion as it increases in size, approaches nearer and nearer to the colour of the skin, becoming perfectly diaphanous.

From the surface of this tumour a pellucid watery fluid sometimes exudes, and this circumstance has been noticed by different authors. It is always attended with a weakness, or, more properly speaking, a paralysis of the lower extremities. The opening of it rashly has proved quickly Talpius, therefore, fatal to the child strongly dissuades us from attempting this operation. Acrel mentions a case where a nurse rashly opened a tumour, which, as she described it, was a blood bag on the back of the child at the time of its birth, in bigness equal to a hen's egg, in two hours after which the child died. From See Spigelia marilandica.

Spigelia anthelmia. The systematic brane, which proceed from a long fissure consisted of a coat, and some strong memname of the spigelia of some pharmaco- of the bones. The extremity of the spinal marrow lay bare, and the spinal duct, in the os sacrum, was uncommonly wide, and distended by the pressure of the waters.

SPIRITUS CAMPHORIE. Spirit of camphor. Formerly known by the names of spiritus camphoraius: Spiritus vinosus camphoratus: Spritus vini camphoratus: " Take of camphor, four onuces; rectified spirit, two pints." Mix, that the camphor may be dissolved. A stimulating medicine, used as an external application against chilblains, rhenmatism, palsy, numbness, and gangrene.

SPIRITUS CARUL Spirit of carraway. Pormerly called aqua seminum carui. " Take of carraway-seeds, bruised, a pound and half; proof spirit, a gallon; water sufficient to prevent empyrcuma. Maccrate for 24 hours, and distil a gallon by a gentle fire The dose is from a fluiddrachm to half an ounce.

SPIRITUS CINNAMONI. Spirit of cinna-Formerly called agua cinnamomi mon. spirituosa. Aqua cinnamomi fortis. "Take of ciunamon bark, bruised, a pound; proof spirit, a gallon; water sufficient to prevent empyreuma." Macerate for 24 hours, and distil a gallon by a gentle fire. Spirit of connamon is mostly used in conjunction with other carminatives to give a pleasant flavour; it may be exhibited alone as a carminative and stimulant. The dose is from a fluiddrachm to half an ounce.

SPIRITUS CORNU CERVI, See Liquor carbonutis ammouix

SPIRITUS JUNIPERI COMPOSITIES, Compound spirit of jumper. Formerly called aqua juniperi composita. "Take of jumperberries, bruised, a pound; carraway-seeds, bruised, fennel-seeds, bruised, of each an ounce and half; water sufficient to prevent empyrcuma." Maccrate for 24 hours, and distil a gallon by a gentle fire.

SPINITUS LAVENDULE. Spirit of laven-Formerly called spiritus laveudula simplex " Take of fresh lavender flowers, two pounds; rectified spirit, a gallon; water sufficient to prevent empyreuma." Maccrate for 24 hours, and distil a gallon by a gentle fire. Though mostly used as a perfume, this spirit may be given internally as a stimulating nervine and antispasmodic. The dose is from a fluiddrachm to balf an ounce.

SPIRITUS LAVENDULA COMPOSITUS. Compound spirit of lavender. Formerly called spiratus lavendule compositus matthie. " Take of spirit of lavender, three pints; spirit of rosemary, a pint; cinnamon bark, bruised, nutmegs, bruised, of each half an ounce; red saunders wood, sliced, an ounce." Macerate for fourteen days, and An elegant and useful antispasmodic, and stimulant in very general use against nervous diseases, lowness of spirits, and weakness of the stomach, taken on a lump of sugar.

SPIRITUS LUMBRICORUM. The spirit obtained by the distillation of the earthworm is similar to hartshorn.

Spirit of SPIRITUS MENTIA PIPERITA. peppermint. Formerly called spiritus menthe piperitidis: Aqua menthe piperitidis spirituosa. " Take of peppermint, dried, a pound and half; proof spirit, a gallon; water sufficient to prevent empyrcuma." Macerate for 24 hours, and distil a gallon by a gentle fire. This possesses all the properties of the peppermint with the stimulating virtues of the spirit. from one fluiddrachm to an ounce.

SPIRITUS MENTILE VIRIDIS, Spirit of spearmint. Formerly called spiritus menthæ sativæ: Aqua menthæ vulgaris spiri-"Take of spearmint, dried, a luosa. pound and half; proof spirit, a gallon; water sufficient to prevent empyreuma." Macerate for twenty-four hours, and distil a gallon. This is most commonly added to carminative or antispasmodic draughts, The dose and seldom exhibited alone. from one fluiddrachm to an ounce.

SPIRITIS MILLEPEDARUM. A fluid volatile alkali, whose virtues are similar to hartshorn.

SPIRITUS MYNDERERI. See Liquor acetatis aumonia.

Spiritus myristica. Spirit of numer. Formerly called agua nucis " Take of nutmegs, bruised, two ounces; proof spirit, a gallon; water sufficient to prevent empyreuma." Maccrate for 24 hours, and distil a gallon by a gentle fire. A stimulating and agreeable spirit possessing the virtues of the nutmeg. dose from one fluiddrachm to an ounce.

SPLEEN. Σπλην. Lien. The spleen or milt is a spongy viscus of a livid colour, and so variable in form, situation, and magnitude, that it is hard to determine either. Nevertheless, in a healthy man it is always placed on the left side, in the left spleen.) Inflammation of the spleen. A hypocondrium, between the eleventh and genus of disease in the class pyrexic and twelftli false ribs. Its circumference is order phlegmasia of Cullen; characterized oblong and round, resembling an oval by pyrexia, tension, heat, tumour, and

It should particularly be remembered of this viscus, that it is convex towards the ribs, and concave internally: also, that it has an excavation, into which vessels are inserted.

It is connected with the following parts: 1. With the stomach, by a ligament and short vessels. 2. With the omentum, and the left kidney. 3. With the diaphragm, by a portion of the peritonaum. 4 With the beginning of the pancreas, by vessels. 5. With the colon, by a ligament.

In man the spleen is covered with one simple, firm membrane, arising from the peritonæum, which adheres to the spleen, very firmly, by the intervention of cellular

See structure.

The vessels of the spleen are, the splenic artery comin from the celiac artery, which, considering the size of the spleen, is much larger than is requisite for the mere nutrition of it. This goes by serpentine movements, out of its course, over the puncreas, and behind the stomach, and after having given off branches to the adjacent parts, it is inserted into the concave surface of the spleen. It is afterwards divided into smaller branches, which are again divided into other yet smaller, delivering their blood immediately to the veins, but emitting it no where else. The veins, at length, come together into one, called the splenic vein, and having received the large coronary vein of the stomacli, besides others, it constitutes the left principal

branch of the vena portæ.

The nerves of the spleen are small; they surround the arteries with their SPIRITUS VOLATILIS FŒTIDUS. See Spi- branches; they come from the particular plexus, which is formed of the posterior

Lymphatic vessels are almost only seen

spleen.

The use of spleen has not hitherto been determined; yet if its situation and fabric be regarded, one would imagine its use to consist chiefly in affording some assistance to the stomach during the progress of di-

which is inserted into the vertebræ of the pieces of sponge in hot melted emplas-neck, splenius colii. We have here follow- trum ceræ compositum, and pressing

them between two iron plates. As soon as cold, the substance thos formed may be cut into pieces of any shape. It was formerly used for dilating small openings, for which it was well adapted, as when the wax melted, the elasticity of the sponge made it expand and distend the opening, in which it had been put. Mr. Cooper informs us that the best modern surgeons seldom employ it.

SPONGIA USTA. Burnt sponge. " Cut the sponge into pieces, and beat it that any extraneous matters may be separated; then burn it in a close vessel until it becomes black and friable; lastly rub it to a very fine powder." This preparation is exhibited with bark in the cure of scrophulous complaints, and forms the basis of a lozenge which has been known to cure the bronchocele in many instances. The dose is from a scruple to a drachm.

SPONGIOSA OSSA. Ossa turbinata inferiora. These bones are situated in the under part of the side of the nose, they are of a triangular form and spongy appearance, resembling the os spongiosum superius; externally they are convex; internally they are concave; the convexity is placed towards the septum nasi, and concavity outwards. The under edge of Signifies that kind of myrrh which distils each bone is placed horizontally near the or falls in drops from the trees. It is also outer part of the nose, and ending in a used by some writers for a more liquid sharp point behind. At the upper part of kind of amber than what is commonly met the bone are two processes, the anterior of with in the shops; whence in Scribonius which ascends and forms part of the la- Largus, Ægineta, and some others, we crymal groove, and the posterior descends meet with a collyrium, and several other and forms a hook to make part of the max- forms, wherein this was the chief ingreillary sinus.

The connexion of this bone is to the os maxillare, os palati and os unguis by a distinct suture in the young subject; but in the adult, by a concretion of substance.

The ossa spongiosa afford a large surface for extending the organ of smell by allowing the membrane of the nose to be expanded, upon which the olfactory nerves are dispersed.

In the fœtus, these bones are almost

complete.

sylves, vis The wild carrot.

STAPHYLOMA. (From saquan; a grape; so n. med from its being thought to resemble a grape.) Staphylosis. A disease of the eye ball in which the cornea loses its natural transparency, rises above the level of the eye, and successively even projects beyond the eye-lids, in the form of an clongated, whitish, or pearl-coloured tuniour which is sometimes smooth, sometimes uneven, and is at ended with a total loss of sight. The proximate cause is an offusion of thick humour between the lamellæ of the cornea, so that the internal and external superfices of the cornea, very much protuberates. The remote causes are, an habitual ophthalmia, great contusion, and frequently a deposition of the variolous humour in the small-pox. The species are:

1st Staphyloma totale, which occupies the whole transparent cornea; this is the most frequent species. The symptoms are, the opaque cornea protuberates, and if in the form of a cone increasing in in guitude, it pushes out and inverts the lower eye lid; and sometimes the morbid cornea is so long elongated, as to lay on the cheek, causing friction and excoria-tion. The bulb of the eye being exposed to the air, sordes generate, the inferior parpebra is irritated by the cilia, and very paintul red and small papilla are observ-

abic.

2nd. Staphyloma racemosum is a staphy-

ness thereunto it is applied to many other doma formed by carnous tubercles, about

3d. Staphyloma partiale, which occupies some part of the cornea: it exhibits an opaque tumour prominent from the cornea, similar to a small blueish grape.

4th. Staphyloma sclerotice, is a bluish tumour attached to some part of the sclerotica, but arising from the tunica albugi-

5th. Staphyloma pellucidum, in which the cornea is not thickened or incrassated, but very much extended and pel-

7th. Staphyloma iridis. For this species see Ptosis widis.

STAR THISTLE. The roots of this plant, Carlina acaulis of Linnaus, are said to be diuretic, and by some recommended in gravel and jaundice.

STARCH. Amylum. The fecula of

wheaten flour. See Amylum

Starch is one of the constituent parts in all mealy farinaceous seeds, fruits, roots, and other parts of plants. Our common starch is made from wheat. It is not necessary that the grain be first bruised in mills. The entire corn, well cleansed, is soaked in cold water until the husk separates; and the grains, having become quite soft, give out by pressure a milky fluid. The grains are then taken out of the water by means of a sieve, put into a coarse linen sack, and transferred into the treading-tub; where they are trodden, after cold water

has been poured upon them.

By this operation the starchy part is washed out, and mingling with the water makes it milky. The water is now drawn off, running through a sieve into the settling tub. Fresh water is again effused upon the grains, and the same operation is continued till the water in the treading-tub is no longer rendered milky. The starch here precipitates by repose from the water that held it suspended; during which, especially in a warm season, the mucilaginous saccharine matter of the flour, that was dissolved by the water, goes into the acetous fermentation. From this cause the starch grows still purer and whiter. The water is next let off from the starch, which is several times more washed with clear fresh water; the remaining part of which is suffered to drip through linen cloths sup ported by hurdles, upon which the wet starch is placed. When the starch has fully subsided, it is wrapt in, wrung between these cloths, or pressed, to extort still more of the remaining liquid.

I' is afterwards cut into pieces, which are laid in airy places on slightly burnt bricks to be completely dried, partly by the free currency of air, and partly by the which cases no conception can take place : bricks imbibing their moisture. Lastly, the outer crust is scraped off, and they are broken into smaller pieces.

In the sacks wherein the corn was trodden there remain its husks and glutinous paris; and this residuum is employed as

food for cattle.

STATICE. (From sation, to stop, so named from its supposed property of restraining hæmorrhages) The name of a genus of plants in the Linnæan system. Class, Pentandria. Order, Pentagynia. The herb sea-thirst.

STERNO. Names compounded of this word belong to muscles which are attached to the sternum; as,

STERNO-CLEIDO HYOIDEUS. See Sterno. hyoideus.

STERNO-CLEIDO MASTOIDEUS. Sterno-mastoideus and cleido-mastoideus of Albinus. Mastoideus of Douglas and Cow. A stationary per, and terno clavio-mastoidien of Dumas. mastord process of the temporal bone, which it surrounds; and gradually becom-STEATOCELE. (From seag, suet, and ing thinner, is inserted as far back as the lambdoidal suture

STERNO COSTALES Vesalius con-STEATOMA. (From stag, suet.) An sidered these as forming a single muscle on encysted tumour, whose contents are of each side, of a triangular shape; hence we find the name of triangularis adopted by The best, hard- Douglas and Albinus; but Verheyen, who the name of sterno costales; and in this he is very properly followed by Winslow,

Haller, and Lietaud.

These muscles are situated at each side of the under surface of the sternum, upon the cartilages of the third, fourth, fifth, and sixth ribs. Their number varies in different subjects; very often there are only three, sometimes five, and even six, but most usually we find only four.

The lowermost of the sterno costales, or what would be called the inferior portion of the triangularis, arises tendinous and fleshy from the edge and inner surface of the lower part of the cartilago ensiformis, where its fibres intermix with those of the diaphragm and transversalis abdominis. tion, and are inserted, by a broad thin ten-

The second and largest of the sterno

times of the fourth rib.

The third arises tendinous from the sides of the middle part of the sternum, near the cartilages of the fourth and fifth ribs, and, ascending obliquely outwards, is inserted into the cartilage of the third rib.

The fourth and oppermost, which is the most frequently wanting, arises tendinous from the beginning of the cartilage of the third rib and the adjacent part of the sternum, and running almost perpendicularly upwards, is inserted by a thin tendon (which covers a part of the second internal intereostal), into the cartilage and beginning of the bony part of the second rib.

All these muscles are more or less intermixed with one another at their origin, and this probably occasioned them to be considered as one muscle. Fallopius inform us, that the plate Vesalius has given of them was taken from a dog, in which animal they are much larger than in man. Donglas has endeavoured to account for this difference, but his explanation is far

from being satisfactory

STERNO HYODEUS. As this mus-cle arises from the clavicle, as well as from the sternum, Winslow calls it sternocleido hyoideus It is a long, flat, and thin muscle, situated obliquely between the sternum and os hyoides, behind the lower part of the mastoideus, and covering the sterno thyroideus and the hyo thyroideus. It arises, by very short tendinous fibres, from the eartilaginous part of the first rib, musele.

Its use is to draw the os hyoides down- rib. wards.

STERNO MASTOIDEUS. See Sternocleido-mastoideus.

STERNO THYROIDEUS. Sterno-thyroidien of Dumas. This is flat and thin, like er. It is situated at the fore part of the neck, between the sternum and thyroid cartilage, and behind the sterno hyoideus. It arises part of the sternum, between the eartil ges as from the clavicle where it joins with the considerable hole, large enough in some sternum. From thence, growing some-subjects to admit the end of the little finwhat narrower, it ascends, and, passing ger. Sylvius seems to have been the first

edge of the cartilage of the fifth, and some- over the thyroid gland and the cricoid cartilage, is inserted tendino is into the lower and posterior edge of the rough line of the thyroid cartilage, immediately under the insertion of the last-described muscle. Now and then a few of its fibres pass on to the os hyordes. Its use is to draw the thyroid cartilage, and consequently the larynx, downwards.

STERNUM. Pectoris os. The breastbone. The sternum os pectoris, or breastbone, is the oblong, flat bone, placed at the fore part of the thorax. The ossification of this bone in the fœtus beginning from many different points at the same time, we find it, in young subjects, composed of several bones united by cartilages; but as we advance in life, most of these cartilages ossify, and the sternim, in the adult state, is found to consist of three, and sometimes only of two pieces, the two lower portions being united into one; and very often, in old subjects, the whole is formed into one bone. But, even in the latter case, we may still observe the marks of its former divisions; so that, in describing the bone, we may very properly divide it into its upper, middle, and inferior portions.

The upper portion forms an irregular square, which without much reason, has, by many writers, been compared to the figure of a heart as it is painted on cards. It is of considerable thickness, especially at its upper part. Its anterior surface is irregular, and slightly convex; posteriorly, from the upper and inner part of the it is somewhat concave. Its upper middle sternum, from the capsular ligament that part is hollowed, to make way for the traconnects hat bone with the clavicle, and chea arteria. On each side, superiorly, commonly from a small part of the clavicle, and chear arteria. On each side, superiorly, commonly from a small part of the clavicle we observe an oblong articulating surface, itself; from thence, ascending along the covered with cartilage in the recent subanterior and lateral part of the neck, we jeet, for receiving the ends of the clavistic inferior part of the larynx, by means of a side, the bone becomes thinner, and we thin membrane, which forms a kind of observe a rough surface for receiving the times alba. After this the two muscles separate again, and each passing over the tothe inferior edge of this, we find the side of the thyroid cartilage, is inserted half of such another surface, which, cominto the basis of the oshvoides, immediate. into the basis of the os hyoides, immediate- bined with a similar surface in the middle ly behind the insertion of the last-described portion of the sternum, serves for the articulation of the cartilage of the second

The middle portion is much longer, narrower, and thinner than the former; but is somewhat broader and thinner below than above, where it is connected with the upper portion. The whole of its antethe preceding muscle, but longer and broad-rior surface is slightly convex, and within it is slightly concave. Its edges, on each side, affords four articulating surfaces, for the third, fourth, fifth, and sixth ribs; and broad and fleshy from the upper and inner parts of articulating surfaces at its upper and lower parts, for the second and seof the first and second ribs, from each of venth ribs. About the middle of this porwhich it receives some few fibres, as well tion of the sternum we sometimes find a

who described it. Riolanus and some others after him have, without reason, supposed it to be more frequent in women than in men. In the recent subject it is closed by a cartilaginous substance; and, as it does not seem destined for the transmission of vessels, as some writers have asserted, we may, perhaps very properly, with M. Hunauld, consider it as an accidental circumstance, occasioned by an interruption of the ossification, before the whole of this part of the bone is completely ossified.

The third and inferior portion of the sternum is separated from the former by a line, which is seldom altogether obliterated, even in the oldest subjects. It is smaller than the other parts of the bone, and descends between the ribs, so as to have been considered as an appendix to the rest of the sternum. From its shape, and its being constantly in a state of cartilage in young subjects, it has been commonly named cartilago xiphoides, ensiformis, or sword-like cartilage; though many of the ancients gave the name of xiphoides to the whole sternum; comparing the two first bones to the handle, and this appendix to the blade of the sword. The shape of this appendix varies in different subjects; in some it is longer and more pointed, in others shorter and more obtuse. Veslingius has seen it reaching as low as the navel, and incommoding the motion of the trunk forwards. In general it terminates obtusely, or in a single point; sometimes, however, it is bifurcated, and Eustachius and Haller have seen it trifid. Very often we find it perforated, for the transmission of branches of the mammary artery. In the adult it is usually ossified and tipped with cartilage, but it very often continues cartilaginous through life, and Haller once found it in this state in a woman who died in her hundredth year.

The substance of the sternum, internally, is of a light, spongy texture, covered externally with a thin bony plate; hence it happens that this bone is easily fractured. From the description we have given of it, its uses may be easily understood. We have seen it serving for the articulation of seven true ribs on each side, and hence we shall find it of considerable use in respiration. We likewise observed. that it is articulated with each of the clavicles. It serves for the origin and insertion of several muscles; it supports the mediastinum; and lastly, defends the heart and lungs; and it is observable, that we find a similar bone in almost all animals that have lungs, and even in such as have no ribs, of which latter we have an instance in the frog.

STERNUTAMENTORIA. See Ptarmica.

STERTOR. A noisy kind of respiration, as is observed in apoplexy. A snoring, or snorting. STHENIA. A term employed by the followers of Dr. Brown, to denote that state of the body which disposes to inflammatory diseases in opposition to those of debility, which arise from asthenia.

STIBIALIA. (From stibium, antimony.) Antimonials. Medicines whose chief ingredient is antimony.

STIBIL ESSENTIA. Antimonial wine.

STIBIUM. (Στιβιον: from 5ιλδω, to shine.) An ancient name of antimony. See Antimonium.

STIGMA. ( $\Sigma \tau i \gamma \mu \alpha$ : from  $\pi i \zeta \omega$ , to inflict blows.) A small red speck in the skin, occasioning no elevation of the cuticle. Stigmata are generally distinct, or apart from each other. They sometimes assume a livid colour, and are then termed petechia.

STILBOMA. (From sine, to polish.) A cosmetic.

STILLICIDIUM. (From stillo, to drop, and cado, to fall) A strangury, or discharge of the urine drop by drop. Also the pumping upon a part.

STIMMI. ZTIMI, Antimony.

STIMULANTS. (Stimulantia, sc. medicamenta; from stimulo, to stir up) Medicines are so termed which possess a power of exciting the animal energy. They are divided into, 1. Stimulantia tonca, as sinapi, contharides. mercurii praparationes. 2. Stimulantia defusibilia, as alkali volatile, electricity, heat, &c. 3. Stimulantia cardiaca, as cinnamomum, nux moschata, wine, &c.

STIMULUS. Any thing which irri-

Stinking lettuce. See Lactuca graveolens.
STIZOLORIUM. The cowage is sometimes so called. See Dolichos.

STOECHAS. (From 5012ades, the islands on which it grew.) French lavender.

STOCKES ARABICA. French lavender. Spica hortulana. Stucadore. Lavendula stæchas of Lunacus. This plant is much less grateful in smell and flavour than the common lavender, to which it is allied in its properties.

STORCHAS CITHINA. See Elichrysum.

STOMACACE. (From 50 µ2, the month, and x2xco, evil.) Canker. A fetor in the mouth, with a bloody discharge from the gums. It is generally a symptom of the scurvy. It is also a name for the scurvy.

STOMACH. (The word stomachus properly belongs to the upper orifice of the stomach, though given to the whole viscus.) Ventriculus. Anocelia. Gaster. Nedys. A membranous receptacle, situated in the epigastric region, which receives the food from the cosophagus; its figure is somewhat oblong and round: it is largest on the left side, and gradually diminishes towards its lower orifice, where it is the least. Its superior orifice, where the cosophagus terminates, is called the cardia; the inferior orifice, where the intestine begins, the trulorus.

The anterior surface is turned towards the ing. An affection of the eye by which abdominal muscles, and the posterior op. person sees objects in an oblique manner, posite the lumbar vertebra. curvatures; the first is called the great Cullen arranges this disease in the class curvature of the stomach, and extends locales, and order dyscinesia. downwards, from one or fice to the other, having the omentum adliering to it; the second is the small curvature, which is also between both orifices, but superiorly and posteriorly. The stomach, like the intestinal canal, is composed of three coats, or membranes: 1. The outermost, which is very firm, and from the peritonzum. 2. The muscular, which is very thick, and composed of various muscular fibres; and, 3. The innermost, or villous coat, which is covered with exhaling and inhaling vessels, and mucus. These coats are connected together by cellular membrane. The glands of the stomach which separate the mucus are situated between the villous and mus. so called from its fibrous roots ) Dutray. cular coat, in the cellular structure. The arteries of the stomach come chiefly from the caliac artery, and are distinguished into the coronary, gastro-epiploic, and short arteries; they are accompanied by veins which have similar names, and which nerves. The lymphatic vessels are distri. smell somewhat resembling that of poppies, buted throughout the whole substance, and proceed immediately to the thoracic The use of the stomach is to excite hunger and partly thirst, to receive the food from the esophagus, and to retain it, till, by the motion of the stomach, the admixture of various fluids, and many other changes, it is rendered fit to pass the right orifice of the stomach, and afford cliyle to the intestines.

Stomach, inflammation of. Sec Gastri-

STOMACHICA PASSIO. A disorder in which there is an aversion to food, even the thought of it begets a nausea, anxiety, cardilagia, an effusion of saliva, and of an a vomiting. Fasting is more tolerable than eating; if obliged to eat, a pain follows that is worse than hunger itself.

STOMACHICS. (Stomachica, sc. medicamenta; from somazos, the stomach.) Medicines which excite and strengthen the

action of the stomach.

STRABALISMUS. See Strabismus.

STRABISMUS. (From sealita, to squint.) Strabalismus. Strabositas. Squint-

It has two from the axis of vision being distorted. He distinguishes three species

1. Strabismus habitualis, when from a

custom of using only one eye.

2. Strabismus commodus, when one eye in comparison with the other, from greater weakness, or mobility, cannot accommodate itself to the other.

Strabismus necessarius, when some change takes place in the situation or figure of the eye, or a part of it

STRABOSITAS See Strabismus.

STRAMEN CAMELORUM. Camel's hay, or juncus odoratus.

STRAMMONIUM. See Stramonium.

STRAMONIUM. (From stramen, straw; Barryo coccalon. Solanum maniacum of Dioscorides, and Stramonium spinosum of Solanum fætidum of Bauhin. Gerard. Strammonium majus album. Common thornapple. Datura stramonium of Linnaus :pericarpirs spinosis erectis ovatis, foliis ovatis term nate in the vena porta. The nerves glabris. This plant has been long known of the stomach are very numerous, and as a powerful narcotic poison. In its re-come from the eighth pair and intercostal cent state it has a bitterish taste, and a especially if the leaves be rubbed between the fingers. Instances of the deleterious effects of the plant are numerous, more particularly of the seed. An extract prepared from the seeds is recommended by Baron Stoerck in maniacal, epileptic, and convulsive affections; and is said by some to succeed, while, in the hands of others, it has failed. In this country, says Dr. Woodville, we are unacquainted with any practitioners whose experience tends to throw light on the medical character of this plant. It appears to us, continues Dr. Woodville, that its effects as a medicine are to be referred to no other power than that of a narcotic. And Dr. Cullen, speaking on this subject, says, "I liave no doubt that narcotics may be a remedy in certain cases of mania and epilepsy; but I have not, and I doubt if any other person has, learned to distinguish the cases to which such remedies are properly adapted. It is therefore that we find the other narcotics, as well as the stramonium, to fail in the same hands in which they had in other cases, seemed to succeed. It is this consideration that has occasioned my neglecting the use of stramonium, and therefore pre-vented me from speaking more precisely from my own experience on this subject."

The extract of this plant has been the preparation usually employed, and from one to ten grains and upwards a day; but the powdered leaves, after the manner of those directed of cicuta, would seem to be

more certain and convenient. Greding found the strength of the extract to vary exceedingly; that which he obtained from Ludwig was much more powerful than that which he had of Stoerk. Externally, the leaves of stramonium have been applied to inflammatory tumours and burns, and it is said with success, and, of late, the dried leaves have been smoked as a remedy in asthma; but it does not appear that they have been more efficacious in this way than tobacco.

STRAMONIUM OFFICINALE. See Stramo-

STRAMONIUM SPINOSUM. See Stramo-

STRANGALIS. (From sear Seve, to tor-A hard painful tumour in the breast, from milk.

STRANGURY. (Stranguria. From searg, a drop, and seor, urine ) A difficulty of making water, attended with pain and dripping. See Ischuria.

STRATIOTES. (From sealos, an army; so named from its virtues in healing fresh wounds, and its usefulness to soldiers.) See Millefolium.

STRATICTICUM. See Millefolium.

Strawberry. See Fragaria.

STREATHAM WATERS. A weak purging water, drunk from one, two, or more pints in a morning.

STREMMA. (Στεεμμα; from σεεφω, to turn ) A strain, or sprain, of the parts

about a joint

STRICTURE. A diminution, or contracted state of some tube, or duct, of the body; as the æsophagus, intestines, urethra, vagina, &c. They are either organical or spasmodic.

Grinding of STRIDOR DENTIUM.

the teeth.

Strigilis. An instrument to STRIGIL. scrape off the sweat during the gymnastic exercises of the ancients, and in their baths; strigils were made of metals, horn, evory, and were curved. Some were made of linen.

STRIGMENTUM The strigment, filth, or sordes, scraped from the skin, in baths and

places of exercises.

Strophos (From seepw, to turn.) A

twisting of the injestines.

A papulous eruption STROFHULUS. pecul ar to infants, and exhibiting a variety of forms, which are described by Dr. bidus, confertus, volutions, and candidus.

1. Strophulus intertinctus, (from inter-

stantly on the cheeks, fore-arm, and back of the hand, but are sometimes diffused over the whole body. The papulæ are, in many places, intermixed with stigmata, and often with red patches of a larger size, which do not, however, occasion any elevation of the cuticle. A child's skin thus variegated, somewhat resembles a piece of red printed linen; and hence this eruption was formerly called the red gown, a term which is still retained in several counties of England, and may be found in old dictionaries. Medical writers have changed the original word for one of a similar sound, but not more significant. strophulus intertinctus has not, in general, any tendency to become pustular, a few small pustules containing a straw-coloured watery fluid, occasionally appear on the back of the hand, but scarcely merit attention, as the fluid is always re-absorbed in a short time, without breaking the cuticle. The eruption usually terminates in scurf, or exfoliation of the cuticle; its duration, however, is very uncertain; the papulæ and spots sometimes remain for a length of time, without an obvious alteration; sometimes disappear and come out again daily; but, for the most part, one eruption of them succeeds another, at longer intervals, and with more regularity. This complaint occurs chiefly within the two first months of lactation. It is not always accompanied with, or preceded by any disorders of the constitution, but appears occasionally in the strongest and most healthy children. Some authors connect it with aphthous ulcerations common in children, supposing the latter to be a part of the same disease diffused along the internal surfaces of the mouth and intestines. The fact, however, seems to be, that the two affections alternate with each other; for those infants, who have the papulous eruption on the skin are less liable to aphthæ; and when the aphthæ take place to a considerable degree, the skin is generally pale and free from eruption. The strophulus intertinctus is, by most writers, said to originate from an acidity, or acrimonious quality of the milk taken into a child's stomach, communicated afterwards to the blood, and stimulating the cutaneous excrctories. This opinion might, without difficulty, be proved to have little foun-dation. The pre-disposition to the com-Willan, under the titles of intertinctus, al- plaint may be deduced from the delicate and tender state of the skin, and from the strong determination of blood to the surtincto, ospothere and there, ) usually called face, which evidently takes place in inthe red gum, and, by the French, Efflores fants. The papulous cruption is, in many cence benigne. The papulæ characterizing cases, connected with a weak, irritable this affection, rise sensibly above the level state of the alimentary canal, and conseof the cuticle, are of a vivid red colour, quent indigestion. For if it be by any and commonly distinct from each other, means suddenly repelled from the surface, Their number and extent varies much in diarrhæa, vomiting, spasmodic affections of different cases. They appear most con- the bowels, and often general disturbance of the constitution succeed; but as soon flammation subsides. In the seventh or as it reappears, those internal complaints eighth, the strophulus conferus assumes are wholly suspended. Dr Armstrong and a somewhat different form; one or two others have particularly noted this reciplarge irregular patches appear on the arms, rocation, which makes the red guin, at shoulder, or neck; in which the papulæ times, a disease of some importance, though are hard, of a considerable size, and set in its usual form, it is not thought to be in so close together, that the whole surface is any respect dangerous. On their remarks of a high red colour. Most commonly the a necessary caution is founded, not to ex- fore arm is the seat of this eruption, the pose infants to a stream of very cold air, nor to plung them unseasonably in a cold and gradually extending upwards along bath. The most violent, and even fatal the arm. Sometimes, however, the erupsymptoms have often been the consequence of such imprudent conduct.

2. The Strophulus albidus, by some termed the white gum, is merely a variety of scrophulus intertinctus, but deserves some notice on account of the different appearance of its papulæ. In place of those described as characterizing the red gum, there is a number of minute, whitish specks, a little elevated, and sometimes, though not constantly, surrounded by a slight redness. These papulæ, when their tops are removed, do not discharge any fluid; it is, however, probable that they are originally formed by the deposition of a fluid, which afterwards concretes under the cuticle They appear chiefly on the face, neck, and breast, and are more permanent than the papulæ of the red gum. In other respects, they have the same na ture and tendency, and require a similar plan of treatment. Although a distinctive name has been applied to this eruption, when occurring alone, yet it is proper to observe that, in a great number of cases, there are red papulæ and spots intermixed with it, which prove its connexion with the strophulus intertinctus.

3. The Strophulus confertus. (From confercio, to crowd together.) An eruption of numerous papulæ, varing in their size, appears on different parts of the body in infants, during dentition, and has thence been denominated the tooth-rash. It is sometimes also termed the rank red gum It is About the fourth or lifth month after birth, an eruption of this kind usually takes place on the checks and sides of the nose, extending sometimes to the forehead and arms, but rarely to the trunk or body. The papulæ on the face are smaller, and set more closely together than in the red gum; their colour is not so vivid, but they are generally more permanent They terminate at length with slight extoliations of the enticle, and often appear again in the same places, a short time afterwards. The papula which, in this complaint, oc- frequently seen the cruption when no such casionally appear on the back or loins, eause was evident. It may, with more are much larger, and somewhat more dis- probability, be considered as one of the tant from each other, than those on the numerous symptoms of irritation arising face. They are often surrounded by an from the inflamed and painful state of the extensive circle of inflammation, and a few of them contain a semi-pellucid watery during that process, and disappears soon Auid, which is reabsorbed when the in- after the first teeth have cut the gums.

papulæ rising first on the back of the hand, tion commences at the elbow, and proceeds a little upwards and downwards on the outside of the arm. It arrives at its height in about a fortnight, the papulæ then begin to fade, and becomes flat at the top, afterwards the enticle exfoliates from the part affected, which remains discoloured, rough, and irregular, for a week or two longer

An obstinate and very painful modification of this disease takes place, though not often, on the lower extremities The papulæ spread from the calves of the legs to the thighs, nates, loins, and round the body, as high as the navel: being very numerous and close together, they produce a continuous redness over all the parts above mentioned.

The cuticle presently, however, shrivelled, cracks in various places, and finally separates from the skin in large pieces. During this process a new cuticle is formed. notwithstanding which the complaint re-curs in a short time, and goes through the same course as before. In this manner successive cruptions take place, during the course of three or four months, and perhaps do not cease till the child is one year old, or somewhat more Children necessarily suffer great uneasmess from the heat and irritation occasioned by so extensive an eruption, yet, while they are affected with it, they often remain free from any internal or febrile complaint This appearance should be distinguished from the intertrigo of infants, which exhibits an uniform, red, smooth, shining surface, without papulæ; and which affects only the lower part of the nates and inside of the thighs, being produced by the stimulus of the urine, &c. with which the child's clothes are almost constantly wetted. The strophulus confertus, where the child is otherwise healthy, is generally ascribed to a state of indigestion, or some feverish complaint of the mother, or nurse. Dr. Willan, however, asserts that he has more gums in dentition: since it always occurs

4. The Strophulus volaticus, (from volo, elevated for about a week, then gradually to fly,) is characterized by an appearance of small circular parches, or clusters of papulæ, arising successively on different parts of the body. The number of papulæ in each cluster is from six to twelve. Both the papulæ and their interstices are of a high red colour. These patches continue red, with a little heat, or itching, for about four days, when they turn brown, and begin to exfoliate. As one patch declines, another appears at a small distance from it; and in this manner the complaint often spreads gradually over the face, body, and limbs, not terminating in less than three or four weeks. During that time the child has sometimes a quick palse, a white tongue, and seems uneasy and fretful. In many cases, however, the eruption takes place without any symptoms of internal disorder. The above complaint has been by some writers denominated ignis volaticus infantum; under this title Astruc and Lorry have described one of the forms of crusta lactea, in which a successive eruption of pustules takes place on the same spot generally about the mouth or eyes, in children of different ages, and sometimes in adults. The mocula volutica infantum mentioned by Wittichius, Sennertus, and Sebizcus, agree in some respect with the strophulus volaticus; but they are described by other German authors as a species of erysipelas, or as irregular efflorescences affecting the genitals of infants, and often proving fatal. The strophulus volations is a complaint by no means frequent. In most cases which have come under Dr. Willan's observation, it appeared between the third and sixth month; in one instance, however, it occurred about ten days after birth, and continued three weeks, being gradually diffused from the cheeks and forehead to the scalp, afterwards to the trunk of the body and to the extremities; when the patches exfoliated, a red surface was left, with slight border of detached cuticle.

5. Strophulus candidus. (From candeo, to shine.) In this form of strophulus, the papulæ are larger than in any of the foregoing species. They have no inflammation round their base; their surface is very smooth and shining, whence they appear to be of a lighter colour than the adjoining cuticle. They are diffused, at a considerable diatance from each other, over the deus loins, shoulders, and upper part of the arms; in any other situation they are sel-

dom found.

year old, and most commonly succeeds lungs. The papulæ continue hard and process to the angle of the lower jaw, and

subside and disappear.

STRUMA. (From strue, to heap up.) This term is applied by some authors to scrofula, and by others to an induration of the thyroid gland, which is endemial to the Tyrolese, Swiss, and others.

STRUMEN. (From struma, a scrophulous tumour.) A herb so called from its uses

in healing strumous tumours.

STRUTHIUM. (From seudos, a sparrow; so named from the resemblance of its flowers to an unfledged sparrow.) The master-wort. See Imperatoria.

STRYCHNOMANIA. (From sguzvos, night. shade, and pavia, madness.) So the ancients called the disorder produced by

eating the deadly nightshade.

STRYCHNOS. (From Teuxw, to torment; so named from its properties of producing insanity.) The name of a genus of plants in the Linnæan system.

STRYCHNOS NUX VOMICA. The systematic name of the tree whose seed is called the

poison nut. See Nux vomica.

STRYCHNOS VOLUBILIS. The systematic name of the tree which is supposed to afford the Jesuits bean. See Faba indica.

STUPEFACIENTIA. (From stupefacio, to

stupely.) Narcotics.

STUPHA. (From 5000, to bind.) Stupa. Stuppa. A stupe; the same as fomenta-

STUPOR. (From stupeo, to be sense.

less.) Insensibility.

STUPOR DENTIUM. Commonly called teeth

STUPPA. See Stupha. Stye. See Hordeolum.

STYGIA. (From Styx, a name given by the poets to one of the rivers in hell.) A water made from sublimate, and directed in old dispensatories, so called from a supposition of its poisonous qualities. Aqua Regia is also thus sometimes called, from its corrosive qualities.

STYLIFORM. (Styliformis; from stylus, a bodkin, and formu, a likeness.) Shaped

like a bodkin, or style.

STYLISCUS. (From suxos, a bodkin.) A

tent made in the form of a bodkin.

STYLO. Names compounded of this word belong to muscles which are attached to the styloid process of the temporal bone; as,

STYLO-CERATO-HYOIDÆUS. See Stylo-hyoi-

STYLO CHONDRO-HYOIDÆUS. See Stylo-hyoi-

STYLO.GLOSSUS. (Musculus stylo-glos-This eruption affects infants about a sus.) Stylo-glosse of Dumas. A muscle situated between the lower jaw and os some of the acute diseases to which they hyoides laterally, which draws the tongoe are liable. Dr. Willan has observed it on aside and backwards. It arises tendinous their recovery from a catarrhal fever, and and fleshy from the styloid process, and after inflammations of the bowels, or from the ligament which connects that along its sides, and is insensibly lost near

STYLO-HYOIDEUS. (Musculus stylo-hyoideus.) Stylo-hyodien f Dumas. A muscle situated between the lower jaw and os hyoides laterally, which pulls the os hyordes to one side and a little upwards

It is a small, thin, fleshy muscle, situated between he styloid process and os hyoides, under the posterior belly and middle tendon of the digastricus near the upper edge

of that muscle.

It arises by a long thin tendon, from the basis and posterior edge of the styloid process, and, descending in an oblique direc- spersed with whitish tears, somewhat like tion, is inserted into the lateral and anterior part of the os hyoides, near its horn.

The fleshy belly of this muscle is usually perforated on one or both sides, for the passage of the middle tendon of the digas-

tricus.

Sometimes, though not always, we find another smaller muscle placed before the stylo-hydideus, which, from its having nearly the same origin and insertion, and the same use, is called stylo-hyoidens-alter It seems to have been first known to Eustachius; so that Douglas was not aware of thiscircumstance when he placed it amongst the muscles discovered by himself. It arises from the apex of the styloid process, and sometimes, by a broad and thin aponeurosis, from the inner and posterior part of the angle of the lower jaw, and is inserted into the appendix, or little horn, of the os hyoides.

The use of these muscles is to pull the os lu oides to one side, and a little upwards.

STYLO-HYOIDEUS ALTER. See Stylo-hyoi

STYLO MASTOID FORAMEN. Foramen stylo-mustoidæum. A hole between the styloid and mastoid process of the temporal bone, through which the portio dura of the auditory nerve passes to the temples

STYLO-PHARYNGEUS. (Musculus style-pharyngeus.) Style-thyre pharyngien of Dumas. A muscle situated between the lower jaw and os hyoides laterally, which dilates and raises the pharynx and thyroid SUBCARBON cartilage upwards. It arises fleshy from tassæ subcarbonas the root of the styloid process, and is inserted into the side of the pharynx and back part of the thyroid cartilage.

STYMATOSIS. priapism.) A violent erection of the penis,

with a bloody discharte.

STYPTERIA. (From 5000, to bind; so called from its adstringent properties.) Alum.

STYPTICS (Medicamenta styptica, from A term given to ςυφω, to adstringe.) those substances which possess the power of stopping hæmorrhages, such as turpentine, alum, &c.

STYRACIFLUA. (From styrax, storax,

is inserted into the root of the tongue, runs and fue, to flow.) Liquid storax. Styrax

STYRAX. (From sugaž, a reed, in which it was used to be preserved.) 1. The name of a genus of plants in the Linnzan system. Class, Decandria. Order, Mono-

2 The pharmacopæial name of the Styrax calamita. Officinal storax. officinalis :- foliis ovatis, subius villosis, ra-cemis simplicibus folio brevioribus. There are two kinds of storax to be found in the shops; the one is usually in irregular compact masses, free from impurmes, of a reddish brown appearance, and intergum ammoniac, or benzoin; it is extremely fragrant, and upon the application of heat readily melts. This has been called storax in lump, red storax; and in separate tears, storax in tears. The other kind, which is called the common storax, is in large masses, very light, and bears no external resemblance whatever to the former storax, as it seems almost wholly composed of dirty saw-dust, caked together by resinous matter. Storax was formerly used in catarrhal complaints, coughs, astlimas, obstructions, &c In the present practice it is almost totally disregarded, not withstanding it is an efficacious remedy in nervous discases.

STERAX ALBA. See Balsamum peruvi-

STYRAX BENZOIN. The systematic name of the tree which affords the gum benzoin. See Benzoin.

STYRAX CALAMITA. Storax in the cane, because it was formerly brought to us in reeds, or cancs. See Surax.

STYRAX COLATA. Strained storax.

STYRAX LIQUIDA. Liquid storax. Liquidambra.

The systematic STYRAX OFFICINALIS. name of the tree which affords the solid styrax See Surax.

STYRAX RUBRA. Red storax, or in the

SUBACETAS CUPRI. See Verdigris. Subacetate of copper. See Verdigris. SUBALARIS VENA. The vein of the axilla

or arm-pit.

SUBCARBONAS POTASSÆ.

SUBCARBONAS FERRI. Sce Carbo-

nas ferri.

SUBCARBONAS PLUMBI. Subcar-(From sua, to have a bonate of lead. Cerusse. White lead. This article is made in the large way in white lead manufactories, by exposing thin shects of lead to the vapour of vinegar. The lead is curled up and put into pots of earthen ware in which the vinegar is, in such a way as to rest just above the vinegar. Hundreds of these are arranged together and surrounded with dung, the heat from which volatilizes the acetic acid, which is decomposed by the lead, and an

imperfect carbonate of lead is formed, sublimo, to raise or sublime.) This chemiwhich is of a white colour. This prepara- cal process differs from evaporation only in tion is seldom used in medicine or surgery being confined to solid substances. It is but for the purpose of making other pre- usually performed either for the purpose parations, as the superacetate. See Pulvis of purifying certain substances, and disencerussæ compositus.

SUBCARTILAGINEUM. (From sub, under, and cartilago, a cartilage.) The hypochondrium, or part of the body which lies under have united with greater difficulty if they

the cartilages of the spurious ribs.

SUBCLAVIAN ARTERY. (From sub, treme division. under, and clavis, a key, because the clavicles were supposed to resemble the key consequently capable of being separated. of the ancients.) The right subclavian in most cases, from fixed matters, so vaarises from the arteria innominata, and rious solid bodies are subjected to a similar proceeds under the clavicle to the axilla. treatment. Fluids are said to distil, and The left subclavian arises from the arch solids to sublime, though sometimes both of the aorta, and ascends under the left are obtained in one and the same operaclavicle to the axilla. The subclavians in tion. If the subliming matter concretes their course give off the internal mammary, into a solid, hard mass, it is commonly the cervical, the vertebral, and the supe- called a sublimate; if into a powdery rior intercostal arteries.

SUBCLAVIAN VEIN, This receives the blood from the veins of the arm, and

runs into the vena cava superior.

SUBCLAVIUS (Musculus subclavius; from sub, under, and clavicula, the channel bone, as being situated under the claviele, or channel bone.) Subclavianus. Costo claviculaire of Dumas. A muscle, situated on the anterior part of the thorax, which pulls the clavicle downwards and forwards. It arises tendinous from the cartilage that joins the first rib to the sternum, is inserted after becoming fleshy into the inferior part of the clavicle, which it occupies from within an inch of the sternum as far outwards as to its connexion, by a ligament, with the carocoid process of the sca-

SUBCRURÆI. Two little muscular slips sometimes found under the crurzus; they are inserted into the capsular ligament which they pull up. The cruræus assists

in extending the leg.

SUBCUTANEOUS GLANDS. Glan-These are sebaceous dulæ subentaneæ. glands lying under the skin, which they perforate by their excretory ducts.

SUBCUTANEUS. The platysma myoides

SUBER. The cork tree. The fruit of this tree, Quercus suber of Linnaus, are much more nutritious than our acorns, and are sweet and often eaten when roasted in some parts of Spain. The bark, called cork, when burnt, is applied as an adstringent application to bleeding piles and to allay the pain usually attendant on hamor- it into the state of very fine powder by rhoids, when mixed with an ointment, the same process which has been directed Pessaries and other chirurgical intruments for the preparation of chalk. are also made of this useful bark.

floats in the middle of the urine.

Sublimate. See Oxymurias hydrargyri. SUBLIMATION.

gaging them from extraneous matters; or else to reduce into vapour, and combine. under that form, principles which would had not been brought to that state of ex.

As all fluids are volatile by heat, and

form, flowers.

The principal subjects of this operation are, volatile alkaline salts; neutral salts, composed of volatile salts and acids, as sal ammoniac, the salt of amber, and flowers of benzoin, mercurial preparations, and sulphur. Bodies of themselves not volatile are frequently made to sublime by the mixture of volatile ones, thus iron is carried by sal ammoniac in the preparations of the flores martialis, or ferrum ammoniacale.

The fumes of solid bodies in close vessels rise but a little way, and adhere to that part of the vessel where they con-

cretc.

SUBLIMIS. See Flexor brevis digitorum pedis, and Flexor sublimis perforatus.

SUBLINGUAL GLANDS. sublinguales vel Bartholiniana vel Rivini. The glands which are situated under the tongue, and secrete saliva. Their excretory ducts are called Riverian from their discoverer.

SUBLUXATIO. A sprain.

SUBMERSION. (Submersio, from sub, under, and mergo, to sink.) Drowning. A variety of the apoplexia suffocata. vages terms it asphyxia immersorum.

SUBMURIAS HYDRARGYRI. muriate of mercury. Calomelas. "Take of oxymuriate of mercury, a pound; purified mercury, by weight one ounce." Rub them together until the metallic globules disappear, then sublime; take ont the sublimed mass, and reduce it to powder, and sublime it in the same manner twice more successively. Lastly, bring

Submuriat, or mild muriat of mercury, is Sublimamentum. (From sublimo, to lift one of the most useful preparations of The pendulous substance which mercury. As an anti-venereal it is given in the dose of a grain night and morning, its usual determination to the intestines being (Sublimatio, from prevented, if necessary, by opium. It is

SUDOR ANGLICUS. Called also Hydrono- drargyrus vitriolutus. ses. Hydropyretos. Gargeatio. The sweating sickness of England; an endemic fever. Dr. Cullen thinks it a species of typhus. This disorder is thus named from its first appearing in this island, and acquires the title of sudor from the patient suddenly breaking out into a profuse sweat, which forms the great character of the disease.

SUDORIFICA. (Sudorifica, sc. medicamenta, from sudor, sweat, and facio, to Hydrotica. Hydrotopsea. A synonym of diaphoretics. See Diaphoretics.

Suffimentum. (From suffimen, a perfume.) Hypocapnisma. A suffumigation,

a perfume

SUFFITUS The same.

SUFFOCATIO HYSTERICA. A convulsive affection of the throat.

SUFFOCATIO STRIDULA. The croup.

SUFFUMIGATION. (Suffumigatio, from sub, under, and fumigo, to cloke.) The burning odorous substances to remove an evil smell, or destroy miasma.

Suffusio. (From suffundo, to pour down; so called because the ancients supposed the opacity proceeded from something running under the crystalline humour.) A cataract.

SUFFUSIO AURIGNOSA. A jaundice.

Sugar. See Saccharum

Sugar of lead. See Plumbi superacetas.

Sugar of milk. A substance pr duced from whey, which, if not sour, contains a satine substance to which this name has been given.

SUGILLATION. (Sugillatio. From sugillo, to stain.) A bruise. A spot or mark made

by a leech or cupping-glass.

SULCUS. A groove or furrow; gene-

rally applied to the bones

SULPHAS. (From sulphur, brimstone.) A sulphate or salt formed by the union of the sulphuric acid with different bases.

Sulphas aluminosus. Alum. See Alumin. SULPHAS AMMONIA. Alkali volatile vitriolatum of Bergman. Jal ammoniacum secretum of Glauber. Vitriolum ammoniacale. This salt has been found native in the neighbourhood of some volcanoes. It is estcemed dirretic and deobstruent, and exhibited in the same diseases as the muriate of ammonia.

SULPHAS CUPRI. Vitriolum cupri. phas. Vitriolum caruleum. Vitriolum Romanum. Cuprum vitriolatum. The sulphat of copper possesses acrid and styptic qualities; is esteemed as a tonic, emetic, adstringent, and escharotic, and is exhibited internally in the cure of dropsies, hæmorrhages, and as a speedy emetic. Externally it is applied to stop hæmorrhages, to hæmor-

proud flesh, and condylomata.

SULPHAS FERRI. See Ferri sulphas. SULPHAS HYDRARGYRI. See Ily.

SULPHAS MAGNESIÆ Sulphas mag. nesiæ parificata. Magnesia vitriolata. Sal cathurticus amarus. Sal catharticum amarum. Suiphate of magnesia. Epsom salt. Bitter purging salt.

The sulphate of magnesia exists in seve. ral mineral springs, and in sea water.

It is from these saline solutions that the salt is obtained; the method generally adopted for obtaining it is evaporation. which causes the salt to crystallize in tetrahedral prisms. It has a very bitter taste, and is soluble in its own weight of water at 60°, and in three-fourths of its weight of boiling water. Sulphate of magnesia, when perfectly pure, effloresces; but that of commerce generally contains foreign salts, such as the muriate of mag. nesia, which renders it so dellquescent that it must be kept in a close vessel or bladder. By the action of heat it undergoes the watery fusion, and loses its water of crystallization, but does not part with its acid. One hundred parts of crystallized sulphate of m gnesia consist of 29.35 parts of acid. 17 of earth, and 53.65 of water. The alkalis, strontia, baryta, and all the salts formed by these salifiable bases, excepting the alkaline muriates, decompose sulphate of magnesia. It is also decomposed by the nitrate, carbonate and muriate of lime.

Epsom salt is a mild and gentle purgative, operating with sufficient efficacy, and in general with ease and safety, rarely occasioning any gripes or the other inconvenicnces of resinous purgatives. Six or eight drachms may be dissolved in a proper quantity of common water; or four, five, or more in a pint or quart of the purging mineral water. These solutions may likewise be so managed as to produce evacuation from the other emunctories: if the patient be kept warm they increase perspiration, and by moderate exercise in the cool air, the urinary discharge. Some allege that this salt has a peculiar effect in allaying pain, as in colic, even independently of evacuation.

It is, however, principally used for the preparation of the carbonate of magnesia. SULPHAS POTASSÆ. See Potassæ sul-

SULPHAS SODÆ. See Sodæ sulphas. SULPHAS ZINCI. See Zinci sulphas.

Sulphate. See Sulphas.

SULPHITE. Sulphis. A salt formed by the combination of the sulphureous acid with different bases: as, aluminous sulphite, ammoniacal sulphite, &c.

Sulphur, which is also bine with charcoal, but unites to phosphoknown by the name of brimstone, is the only simple combustible substance which nature offers pure and in abundance. It was the first known of all. It is found in the earth, and exists externally in depositions, in sublimed incrustations, and on the surface of certain waters, principally near burning volcanoes. It is found combined with many nictals. It exists in vegetable substances, and has lately been discovered in the albumen of eggs.

Sulphur in the mineral kingdom is either in a loose powder, or compact; and then either detached or in veins. It is found in the greatest plenty in the neighbourhood of volcanoes or pseudo-volcanoes, whether modern or extinct as at Solfatara, &c. and is deposited as a crust on stones contiguous to them, either crystallized or amorphous. It is frequently met with in mineral waters, and in caverus adjacent to volcanocs; sometimes also in coal-mines. It is found in combination with most of the metals. When united to iron it forms the mineral called martial pyrites, or sulphur purites. Alf the ores known by the name of pyrites, of which there are a vast variety, are combinations of sulphur with different metals; and hence the names of copper, tin, arseniacal, &c. pyrites. It exists like-wise in combination with alumine and lime; it then constitutes different kinds of vapour proceeds. schistus, or alum ores.

Physical properties.—Sulphur is a combustible, dry, and exceedingly brittle body, of a pale lemon-yellow colour. Its specific gravity is 1990. It is destitute of odour, except when rubbed or heat-vessel of cast iron, containing water, is ed. It is of a peculiar faint taste. frequently crystallizes in entire or trunented octahedra, or in needles. If a piece of sulphur of a considerable size, be very gently heated, as for example, by holding it in the hand and squeezing it firmly, it breaks to pieces with a crackling noise. It is a non-conductor of electricity, and hence When it becomes electric by friction. heated, it first softens before it melts, and its fusion commences at 180° Fahr.; at 289° it becomes volatilized, and takes fire at 302°. In the beginning of fusion it is very fluid, but by continuing the heat it grows tough, and its colour changes to a reddish brown. If in this condition it be poured into water, it remains as soft as wax, and yields to any impression. In time however it hardens again and recovers its former consistence.

It unites with most of the earths and with all alkalis, and becomes soluble, when thus combined, in water. It unites to most of the metals, and renders them brittle and fusible. It is soluble in oils; water takes up a minute quantity, as does name is nothing but sulphur finely powardent spirit by means of heat. It dis- dered.

rus by fusion.

Sulphur, like all combustible bodies burns in proportion to the quantity of oxigen which combines with it. Sulphur, beated in a close vessel, sublimes without alteration. It is not changed by exposure to air. It is attacked by the nitric acid when poured on it in its fised state.

If melted sulphur be exposed in the open air to an increase of heat, it takes fire and burns with a blue flame and suffocating vapour. The result of this combustion is sulphurcous acid According to he slow or rapid combustion, it absorbs different quantities of oxigen, and the produced acid

differs in its properties.

Method of obtaining sulphur .- A prodigious quantity of sulphur is obtained from Solfatara in Italy. This volcanic country every where exhibits marks of the acency of subterrancous fires; almost all the ground is bare, and white; and is every where sensibly warmer than the atmosphere, in the greatest heat of summer; so that the feet of persons wasking there are burnt through their shoes. It is impossible not to observe the sulphur, for a sulphureous vapour which arises through different apertures is every where perceptible, and gives reason to believe that there is a subterraneous fire underneath from which that

From pyrites sulphur is extracted in the large way by the following process:

Pyrites is broken into small pieces, and put into large earthen tubes which are exposed to the heat of a furnace. A square It connected as a receiver with the tube in the furnace. The action of the fire proceeds, and the sulphur, being thus melted, is gradually accumulated on the water in the receiver. It is then removed from this receiver, and melted in large iron ladles; in consequence of which, the earthy parts with which it was contaminated are made to subside to the bottom of the ladle, leaving the purified sulphur above. It is then again melted and suffered to cool gradually, in order to free it from the rest of the impurities. It is then tolerably pure, and constitutes the sulphur we meet with in large masses or lumps in the market.

In order to form it into rolls, it is again melted and poured into cylindrical wooden moulds, in these it takes the form in which we usually see it in commerce, as roll sulphur.

Flowers of sulphur, as they are called, are formed by subliming purified sulphur with a gentle heat in close rooms, where the sublimed sulphur is collected, though the article met with in general under that

" Method of purifying sulphur .- Take one part of flowers of sulphur, boil it in twenty parts of distilled water in a glass vessel for about a quarter of an hour; let the sulphur subside, decant the water, and then wash the sulphur repeatedly in distilled water: having done this, pour over it three parts of pure nitro-muriatic acid, diluted with one part of distilled water, boll it again in a glass vessel for about a quarter of an hour, decant the acid, and wash the sulphur in distilled water till the fluid passes tasteless, or till it does not change the blue colour of tincture of cabbage, or litmus. The sulphur thus carefully treated is pure sulphur fit for philosophical experiments.

Sulphur has been long an esteemed article of the Materia Medica; it stimulates the system, loosens the belly, and promotes the insensible perspiration. It pervades the whole habit, and manifestly transpires through the pores of the skin, as appears from the sulphureous smell of persons who have taken it, and from silver being stained in their pockets of a blackish colour. In the stomach it is probably combined with hydrogen. It is a celebrated remedy against cutaneous diseases, particularly psora, both given internally and applied externally. It has likewise been recommended in rheumatic pains, flying gout, rickets, atrophy, coughs, asthmas, and other disorders of the breast and lungs, and particularly in catarrhs of the chronic

In hæmorrhoidal affections it is almost specific; but in most of these cases it is advantageously combined with some cooling purgative, especially supertartrate of potash.

The preparations of sulphur directed to be used by the London and Edinburgh Colleges, are the Sulphur lotum, Sulphur præcipitatum, and Sulphur sublimatum

SULPHUR ANTIMONII PRÆCIPITA. TUM. Sulphur auratum antimonii. preparation of antimony appears to have rendered that called kermis mineral unnecessary. It is a yellow hydro-sulphuret of antimony, and therefore called hydro-sulphuretum stibii luteum, in the new chemical nomenclature. As an alterative and sudorific it is in high estimation, and given in diseases of the skin and glands; and, joined with calomel, it is one of the most powerful and penetrating alteratives we are in possession of.

SULPHUR AURATUM ANTIMONII. See Sul-

phur antimonii præcipitatum.

SULPHUR LOTUM. Washed sulphur. Flores sulphuris loti. "Take of sublimed the metals, and has a weak attraction to sulphur, a pound." Four on boiling water alkalis and earths. It has the property entirely washed away; then dry it. The Priestley, Bergman, Berthollet, &c. say dose is from half a drachm to two that at high temperatures it deposits suldrachms.

SULPHUR PRÆCIPITATUM. Lac sulphuris. " Take of sublimed sulphur, a pound, fresh lime, three pounds" Boil the sulphur and lime together in water. then strain the solution through paper, and drop in as much muriatic acid as may be necessary to precipitate the sulphur; lastly, wash this by repeated affusions of water until it is tasteless. This preparation is mostly preferred to the flowers of sulphur. in consequence of its being freed from its impurities. The dose is from half a drachm to three drachms.

gen gas, sulphurated.

Sulphuretum. A combination of sulphur with different alkaline,

earthy, and metallic bases.

SULPHUREOUS ACID GAS. Several philosophers have paid attention to the properties of this gas, and its combinations; but Berthollet was the first who published an accurate account of it, which Fourcroy and Vauquelin, have investigated still more completely. Their paper is inserted in the Annales de Chimie, II. 54, and copied into Nicholson's Journal, vol. 1. p. 313.

When sulphur is united to oxigen it forms an acid. When the quantity of oxigen is sufficient to oxigenate a given quantity of sulphur completely, the result is a perfect acid called sulphuric acid. If a less quantity of oxigen is made use of, the result is an imperfect acid, capable of taking the gazeous state. To this gazeous fluid the name of sulphureous acid gas is given. It becomes obvious from this, that sulphureous acid gas has the same relation to sulphuric acid as phosphorous acid has to the phosphoric acid. At least this gas occupies the middle place between sulphur

and sulphuric acid.

Properties .- Sulphureous acid gas is a permanently elastic aëriform fluid at the ordina. ry pressure and temperature of our atmosphere. Its odour is strong and suffocating. It cannot maintain combustion, nor the respiration of animals. Its weight is more than double that of atmospheric air. Its specific gravity according to Bergman is 0.00246, and 0 00251, according to Lavoisier. It is not inflan mable. One hundred cubic inches of it weigh nearly 63 grains. It is composed, according to Fourcroy, of 85 sulphur and 15 oxigen. It is acid; it first reddens and then destroys the greater part of the vegetable colours. It exerts little action on so that the acid, if there be any, may be of whitening silk and giving it a lustre. phur, but Fourcroy and Vauquelin, in con-

sequence of some new experiments, deny this assertion. Phospho us has no action upon it. Its attraction for oxigen when dry, at the common temperature, is very feeble, but, if the smallest quantity of moisture be present, the union of the two gases is much favoured. At high temperatures the combination is more speedily cffected. When a mixture of sulphureous acid gas and oxigen gas is made to pass through an ignited tube, the two gases combine and sulphuric acid is formed. When passed into water cooled down to the freezing point, the union is very rapid. Water cooled to forty degrees absorbs onethird part of its weight of sulphureous acid gas. It speedily melts ice. Water saturated with it may be frozen without parting with its gas; but when water, which has been saturated with it, is exposed to heat, it is filled with a vast number of bubbles which continually increase and rise to the surface; these bubbles are the gas separating from it. It is absorbed by oil, ether, and sulphuric acid, the latter when saturated with it acquires the property of smoaking when exposed to air; its colour is altered to a yellowish brown, and its odour is penetrating like that of the gas. When the acid thus saturated with the gas is exposed a few degrees below the freezing point, in congeals or freezes into a crystalline mass. The same happens when submitted to distillation. It decomposes nitric and oxigenated muriatic acid, and dissolves camphor. Sulphurcous acid gas and hydrogen gas have no action upon cach other at common temperatures, but if they are passed through an ignited tube, a decomposition is effected. Charcoal likewise decomposes sulphureous acid gas at a high temperature. Monge and Clouet affirm that by extreme artificial cold and a strong pressure excrted at the same time, they rendered sulphurcous acid gas fluid.

Methods of obtaining sulphureous acid gas. -1. Take one part of mercury and four of concentrated sulphuric acid; put them into a glass retort connected with the pneumatic quicksilver-trough and apply the heat during the slow combustion of sulphur. of a lamp to the mixture till it boils. On continuing the heat after the mercury has been acted upon, sulphureous acid gas will

he obtained in abundance.

comes converted into an oxid; the sul- liquor, by the ammonia and sulphur pluric acid in consequence of the loss of uniting whilst in a state of gas during disoxigen, becomes converted into sulphu- tillation. It excites the action of the abreous acid, which takes the gazeous form sorbent system and diminish arterial acat the common temperature.

2. Sulphurcous acid gas may likewise be obtained by the slow combustion of sul-

Put pounded sulphur into a shallow earthen dish or crucible; melt and set fire to it; neous diseases.

and when it is completely inflamed cover it with a large bell-glass perfectly dry; remove the whole on a dish and surround the apparatus with mercury The sulphur will burn for some time, and the bell-glass will be filled with white vapour. When the vapour has subsided, the gas may be transferred as usual.

SUL.

Explanation .- During the burning of the sulphur in a confined quantity of atmospheric air, it absorbs the oxigen contained in it; this however, not being sufficient to oxigenate the sulphur completely, the result is an imperfect aëriform acid, or sul-

phureous acid gas.

3. Sulphureous acid gas may also be obtained by decomposing sulphite of potash or soda, either by heat alone, or by the affusion of acids.

4. If charcoal be moistened with sulphuric acid, and then exposed to distillation, the products are carbonic acid gas

and sulphureous acid gas.

During this operation the charcoal attracts part of the oxigen of the sulphuric acid, and forms carbonic acid gas. The sulphuric acid is therefore partly de-oxidated and becomes converted into sulphureous acid gas.

5. Sulphureous acid gas is likewise formed by distilling sulphur with the oxids of mercury, lead, tin, manganese, &c.

In these processes the sulphur attracts the oxigen of the metallic oxids, and becomes converted into sulphureous acid gas, while the oxids are partially restored to the metallic state.

Water impregnated with sulphureous acid gas forms

SULPHUREOUS ACID.

1. To prepare sulphureous acid, take one part of mercury and four of concentrated sulphuric acid, put them into a retort furnished with a receiver, and connected with Burkitt's or Pepys's apparatus. The sulphureous acid gas which is disengaged is absorbed by the water in the vessel, and constitutes sulphureous acid.

2 Sulphureous acid is likewise formed

The salts formed by the combination of sulphureous acid with different bases, are called sulphites.

ment of the liver.

Suspensorius Testis. The cremaster muscle of the testicle.

Susurrus. (From susurro, to murmur.) An imaginary sound in the ear.

SUTURE. (Satura, from suo, to join together.) Called also clavata comnissura 1. In surgery this term signifies the uniting the lips of a wound by sewing. A number of different kinds of sutures have been recommended by writers on surgery, but all of them are now reduced to two: namely, the twisted, and the interrupted, called also the knotted suture. The twisted suture is made in the following manner: having brought the divided parts nearly into contact, a pin is to be introduced from the outside inwards, and carried out through the opposite side to the same distance from the edge that it entered at on the former side; a firm wax ligature is then to be passed around it, making the figure of 8, by which the wounded parts are drawn gently into contact. The number of pins is to be determined by the extent of the wound; half an inch, or at most three quarters, is the proper distance between two pins. The interrupted suture is practised where a number of stitches is required, and the interruption is only the distance between the stitches.

2. In anatomy the word suture is applied to the union of bones by means of dentiform margins, as in the bones of the crani-See Temporal, sphenoidal, zygomatic, transverse, coronal, lambdoidal, and sarttal

ni and Swietenia.

Swine pox See Varicella.

SYCOMA. (From ounn, a fig.) or excrescence resembling a fig.

Sycosis. The ophthalmia trachoma of Sauvages; also a fungous ulcer; and by others the tumour on the anus called marisca.

Sylvenium. Asafætida is so termed by most commonly lower than its natural some writers. See Asafatida.

SYMBLEPHARUM. (From our, with, and Brepager, the eyelid.) A concretion of the ey ha to the globe of the eye; also a concretion of the palpebra with the eyc. This chiefly happens in the superior, but very rarely in the inferior palpebra. The causes of this concretion are a bad conformation of the parts, or from ulcers of the cornea, the membrana conjunctiva, or internal superfices of the palpebræ, or imprudent scarifications, or burns, especially if the eye remains long closed. There are two species, the partial, or total; in the former the adhesion is partial, in the latter, the membrana conjunctiva and cornea are concreted together

SYMBOLE. (From συμβαλλω, to knit together.) Is said either of the fitness of parts with one another, or of the consent

nerves, and the like.

SYMBOLOGIA. (From συμβολον, a sign, and xoyor, a discourse.) The doctrine of the signs and symptoms of disease.

SYMMETHY. The exact and beautiful

proportion of parts to one another Sympathetic nerve. See Intercostal nerve. SYMPATHY. (From συμωσσχω, to suffer together, to sympathise.) Sympathia. All the body is sympathetically connected together, and dependent, the one part upom the rest, constituting a general sympathy. But sometimes we find particular parts more intimately dependent upon each other than upon the rest of the body, constituting a particular sympathy. Action cannot be greatly increased in any one organ, without being diminished in some other; but certain parts are more apt to be affected by the derangement of particular organs than others; and it was the observance of this fact which gave foundation to the old and well-known doctrine of sympathy, which was said to proceed, "tum ob communionem et similitudinem generis, tum ob viciniam." It may be thought that this position of action being diminished in one organ, by its increase, either in the rest or in some other part, is contradicted by the existence of general diseases or actions affecting the whole sys-But in them we find, in the first place, that there is always some part more affected than the rest. This local affection is sometimes the first symptom, and affects the constitution in a secondary way, either by the irritation which it produces, or by an extension of the specific action. At other action in the uterus, we diminish that of times the local affection is coevel with the the breasts, and destroy the secretion of general disease, and is called sympathetic. It is observed in the second place, that inflammation of the uterus, which is incias there is some part which is always dent to lying-in women. When the oterus

standard. From the extensive sympathy of the stomach with almost every part of the body, we find that this most frequently suffers, and has its action diminished in every disease, whether general or local, provided that the diseased action arises to any considerable degree. There are also other organs which may, in like manner, suffer from their association or connexion with others which become diseased. Thus, for instance, we see, in the general disease called puerperal fever, that the action of the breasts is diminished by the increased inflammatory action of the uterus.

In consequence of this balance of action, or general connexion of the system, a sudden pain, consequent to violent action of any particular part, will so weaken the rest as to produce fainting, and occasionally death. But this dependence appears between them by the intermediation of more evidently in what may be called the smaller systems of the body, or those parts which seem to be more intimately connected with each other than they are with the general system. Of this kind is the connexion of the breasts with the uterus of the female; of the urethra with the testicles of the male; of the stomach with the liver; and of the intestines with the stomach, and of this again with the brain; of the one extremity of the bone with the other; and of the body of the muscle with its insertion; of the skin with the parts below it.

These smaller systems, or circles, shall be treated regularly; but, first, it may be proper to observe, that these are not only intimately connected with themselves, but also with the general system, an universal sympathy being thus established.

That there is a very intimate connexion between the breast and uterus has been long known; but it has not been very satisfactorily explained. Fallopius, and all the older authors, declare plainly that the spmpathy is produced by an anastomosis of vessels; Bartholin adding, that the child being born, the blood no longer goes to the uterus, but is directed to the breast and changed into milk. But none of all those who talk of this derivation, assign any reasonable cause which may produce it.

In pregnancy, and at the menstrual periods, the uterns is active; but, when the child is delivered, the action of the uterus subsides, whilst the breasts in their turn become active, and secrete milk.

If, at this time, we should again produce milk, as is well illustrated by the case of in the effected than the rest, so also at the cessation of the menses, ceases to be is there some organ which has its action, active, or to secrete, we often find that in consequence of this, diminished lower the breasts have an action excited in them, that that of the rest of the extern and becoming slowly inflamed, and assuming

breasts seem to be a set of glands balanc-ing each other in the system, one only weakness of the testicles, or diminished being naturally active, or secreting proper- action, is induced. In those parts which ly at a time; and accordingly we seldoin, if exhibit this natural association of action. ever, find that when the uterus yields the menstrual discharge, the milk is secreted in perfection, during the continuance of this discharge, nor do we ever find them both inflamed at the same time.

The uterus has not only this connexion with the breasts, but it has also a very particular sympathy with the stomach, which again sympathises with the brain; and thus we see how a disorder of the uterus may induce an extensive series of affections, each dependent on the other.

The organs of generation in the male form likewise a little system, in which all the parts exhibit this sympathy with each other. They likewise give us a very good instance of the association of action, or sympathy, in the common acceptation of that word.

Sympathy is divided into, first, the sympathy of equilibrium, in which one part is weakened by the increased action of another; and, secondly, the sympathy of association, in which two parts act together at the same time.

The sympthy of association is produced suddenly, and for a short time. The sympathy of equilibrium is produced more slowly, and continues to operate for much longer time.

It is curious enough that most, or at least many, of those organs, which seem to be connected by the sympathy of equilibrium, exhibit likewise more or less of the sympathy of association, when under the circumstances in which this can take

The sympathy of equilibrium is seen in the effects of inflammation of the end of the urethra on the testicle; which often diminishes its action, and produces a very disagreeable sensation of dullness, or, if this inflammation be suddenly diminished, the action of the testicle is as suddenly increased, and swelling takes place. The same is seen in the connexion of the urethra with the bladder and prostate gland, as is mentioned in all the disservations on These parts likewise affect gonorrhœa. the stomach greatly, increased action in them weakening that organ much. This is seen in the effects of swelled testicle, or excessive venery, or inflamed bladder, and in a stone; all which weaken the dram drinkers, and in those who stay long stomach, and produce dyspepsia. The in warm countries and use freedoms with same remark applies to the kidney; vo- the stomach. The liver likewise sympamiting and flatulence being produced by

stance of sympathy in the common accep- puration have been often known to take tation of the word, is likewise seen in the place in the liver. connexion betwixt the glands and testicles in coition; but for this purpose, the ac- with the liver, it is also very intimately de-

a cancerous disposition. The uterus and tion in the glands must be sudden and of if the action of one part be suddenly and for a short time increased, the action of the sympathising part will likewise be increased; as we see in the instance already given of coition, and likewise in paroxysms of the stone, in which the glans penis, after making water, becomes very painful.

But if the action be more slowly induced, and continued for a long time, then this association is set aside, by the stronger and more general principle of the equilibrium of action, and the sympathising part is weakened. Hence, violent inflammation of the end of the wrethra produces a weakness and irritability of the bladder, dull-

ness of the testicle, &c.

There is also an evident sympathy of equilibrium betwixt the stomach and lower tract of intestines; which two portions may he said in general to balance each other in the abdomen. When the action of the intestines is increased in diarrhæa, the stomach is often weakened, and the patient tormented with nausea. This will be cured, not so easily by medicines taken into the stomach, as by anodyne clysters, which will abate the action of the intestines. When the intestines are inflamed, as in strangulated hernia, vomiting is a never-failing attendant.

When again the stomach is inflamed, the intestines are affected, and obstinate costiveness takes place; even in hysterical affections of the stomach, the intestines are often deranged. Injections of cold water frequently relieve these affections of the stomach, by their action of the intes-

The liver and stomach are also connected with one another. When the liver is inflamed, or has its action increased, the stomach is weakened, and dyspeptic symptoms take place. When the stomach is weakened, as, for instance, by intoxication, then the action of the liver is increased, and a greater quantity than usual of bile is secreted. The same takes place in warm climates, where the stomach is much debilitated.

If the liver has its action thus frequently increased, it assumes a species of inflammation, or becomes, as it is called, scirrhous. This is exemplified in the habitual thises with the brain; for when this organ is injured, and its action much impaired, The sympathy of association, or an in- as in compression, inflammation and sup-

Besides this connexion of the stomach

pendent on the brain, being weakened by sore, however large the discharge, when the action of the brain is increased, (which is always thin, and accompanied as we see in inflammation of that organ, with little action,) does no good, but only The brain again is affected with pain, when adds to the misery of the patient. or other causes; and this pain will be often relieved by slowly renewing the action of the stomach, by such stimuli as are natural to it, such as small quantities of soups frequently repeated. A slight increase of action in the stomach, at least if not of a morbid kind, affects the brain so as to produce sleep, diminishing its action. This we see in the effects of a full meal, and This even of a draught of warm water The stomach likewise sympath ses with the throat, squeamishness and anorexia being often produced by inflammation of the tonsils This inflammation is frequently abated by restoring or increasing the action of the stomach. Hence the throat, in slight inflammation, is frequently easier after danner; hence, likewise, the effects of emetics in cynanche.

The extremities of bones and muscles also sympathise in the same manner. When one end of a bone is inflamed, the action of the other is lessened, and pain is produced; for a painful sensation may result both from increased and diminished action. When the tendon of a muscle is inflamed, the body of that muscle often is

pained, and vice versa.

Lastly, the external skin sympathises with the parts below it. If it be inflamed, as in erysipelas, the parts immediately beneath are weakened, or have their natural action diminished. If this inflammation affect the face, or scalp, then the brain is injured; and head ache, stupor, or delirium, supervene. If it attack the skin of the abdomen, then the abdominal viscera are affected, and we have voniting and purging, or obstinate costiveness, according to circumstances. This is illustrated by the disease of children, which is called by the women the bowel-hive, in which the skin is inflamed, as they suppose, from some morbid matter within

If the internal parts be inflamed, the action of the surface is diminished, and, by increasing this action, we can lessen or remove the d sease below; as we see daily proved by the good effects of blisters. When the stomach, intestines, or kidney, have been very irritable, a sinapism has been known to act like a charm; and, in the deep seated inflammations of the breasts, howels, or joints, no better remedy is known, after the use of the lancet,

than blisters.

The utility of issues in diseases of the lungs, the liver, and the joints, is to be explained on the same principle. In these explained on the same principle. In these unite and close the lips of wounds toge-cases we find that issues do little good unther.) 1 The name of a genus of plants less they be somewhat painful, or be in the in the Linnxan system. Class, Pentandria, state of healthy ulcers. An indolent flab. Order, Monogynia.

the stomach is weakened by intoxication, may, however, err on the other hand by making the issues too painful, or by keeping them active too long, for, after they have removed the inflammatory disease below, they will still operate on these parts, lessening their action, and preventing the healing process from going on properly. This is seen in cases of curvature of the spine, where at first the inflammation of the vertebra is diminished by the issues; but, if they be kept long open after this is removed, they do harm. see the patient recover rapidly after his surgeon has healed the issue in despair, judging that it could do no farther service, but only increase the weakness of his pa-

> It is a well-established fact, that when any particular action disappears suddenly from a part, it will often speedily affect that organ which sympathises most with the part that was originally diseased. This is best seen in the inflammatory action, which, as practical writers have well observed, occasionally disappears quickly from the part first affected, and

then shews itself in some other.

From the united testimony of all these facts, Mr. Burns, of Glasgow, maintains the doctrine just delivered, and proposes to introduce it into pathological reasonings. In the whole of the animal economy, we discover marks of the wisdom of the Creator, but perhaps in no part of it more than in this, of the existence of the sympathy of equilibrium, for if a large part of the system were to have its action much increased, and all the other parts to continue acting in the same proportionate degree as formerly, the whole must be soon exhausted; (for increased action would require for its support an increased quantity of energy )

But upon this principle, when action is much increased in one part, it is to a certain degree diminished in some other, the general sum or degree of action in the body is thus less than it otherwise would be, and consequently the system suffers

SYMPHISIS. (From our, together, and φυω, to grow.) Mediate connexion. A genus of the connexion of bones, in which they are united by means of an intervening body. It comprehends four species, viz. synchondrosis, syssarcosis, syneurosis, and syndenmosis

SYMPHYTUM. (From unite; so called because it is supposed to

2. The pharmacopæial name of the consolida major. Comfrey This plant, Symphytum officinale :- folis ovatis lanceolatis decurrentibus, is administered where the althæa cannot be obtained, its roots abound. ing with a viscid glutmous juice whose virtues are similar to that of the althau.

SYMPHYTUM MACULOSUM. See Pulmona-

SYMPHYTUM MINUS. See Prunella.

SYMPHYTUM OFFICINALE. The systematic name of the comfrey. See Symphy-

SYNANCHE. See Cynanche.

SYNANCHICA. (From συναγχη, the quinsey; so called from its uses in that dis-

case.) Quinsey-wort.

SYNARTHROSIS. (From συν, together, and αρθρον, a joint.) Immoveable connexion. A genus of connexion of bones, in which they are united together by an immoveable union. It has three species, viz. suture, harmony, and gomphosis.

SYNASTOMOSIS Is used in the same sense

as Anastomosis.

SYNCHONDROSIS. (From our, with, and xordros, a cartilage.) A species of symphysis, in which one bone is united with another by means of an ntervening cartilage, as the vertebræ and the bones of the pubis

SYNCHONDROTOMIA (From our xordpa. sis, the symphisis of the pubis, and Temva, to cut.) The operation of dividing the

symphisis of the pubis.

SYNCHYSIS. (From συίχυω, to confound.) A solution of the vitreous humour into a fine attenuated aqueous fluid. In Cullen's Nosology it is a variety of his species caligo pupilla.

SYNCIPITIS OSSA. See Parietal bones.

SYNCIPUT. The forepart of the era-

SYNCOPE. (Prom our, with, and nowla, to cut, or strike town.) Animi deliquium. Leipothymia. Fainting or swooning. A genus of disease in the class neuroses and order adynamic of Cullen, in which the respiration and action of the heart either cease, or become much weaker than usual, with paleness and coldness, arising from diminished energy of the brain, or from organic affections of the heart. Species: 1. Syncope cardiaca, the cardiac syncope, arising without a visible cause, and with violent palpitation of the heart, during the intervals, and depending generally on concretion and coarctation of the pupilsome organic affection of the heart or It is known by the absence of the pupil, neighbouring vessels. 2 Syncope occa- and a total loss of vision. sionalis, the existing cause being mani- are:

a ligament, and nofes, a discourse.) The found. doctrine of the ligaments.

SYNDESMO-PHARYNGEUS. See Constrictor phoryngis medius

SYNDESMOSIS. (From ourdes mos, a ligament.) That species of symphisis or mediate connexion of bones in which they are united by ligament, as the radius with the ulna.

SYNDESMUS. (From ourdew, to bind to.

gether ) A ligament.

SYNECHIA. Durexia. A concretion of the iris with the cornea, or with the capsule of the crystalline lens. The proximate cause is the contact from inflamma. tion or adhesion of these parts, the consequence of inflammation. The remote causes are, a collapse of the cornea, a prolapse of the iris, a swelling or tunified cataract, hypopium, or a natural formation. The species of this disorder

1. Synechia anterior totalis, or a concretion of the iris with the cornea. This species is known by inspecting the parts. The pupil in this species is dilated or coarctated, or it is found concreted; from whence

various lesions of vision.

2. Synechia anterior partialis, when only some part of the iris is accreted. This concretion is observed in one or many places; from hence the pupil is variously disfigured, and an inordinate motion of the pupil is perceived.

3. Synechia unterior composita, when not only the whole iris, but also a prolapse of the crystalline lens, unites with

the cornea.

4. Synechia posterior totalis, or a concretion of the whole uvea, with the ciliary processes and the capsule of the crystalline

5. Synechia posterior partialis, when only some part of the capsule of the crystal. line lens is concreted with the uvea and cornea. This accretion is simplex, duplex, triplex, or in many places it may happen.

6. Synechia complicata, with an amaurosis, cataract, mydriasis, myosis, or syne-

SYNEUROSIS. (From our, with, veuper, a nerve, because the ancients included membranes, ligaments, and tendons, under the head of nerves.) A species of symphisis, in which one bone is united to another by means of an intervening membrane.

SYNIZESIS. Confidentia. A perfect The species

1. Synizesis nativa, with which infants See Angina pec- are sometimes born. In this case, by an error of the first conformation of the pupil, SYNDESMOLOGIA. (From συνδεσμος, there is no perforation; it is very rarely

2. Synizesis accidentalis, a concretion of

787

the pupil, from an inflammation or ex- and unquenchable thirst, oppression of ulceration, of the uvea or iris, or from breathing, and nausea. The kin is dry a defect of the aqueous or vitreous hu

3. Synizesis, from a secession of the iris or cornea. From whatever eause it may happen, the effect is certain, for the pupil contracts its diameter; the longitudinal fibres, separated from the circle of the cornea, cannot resist the orbicular fibres: from hence the pupil is wholly or partially

4. Synizesis complicata, or that which is complicated with an amaurosis, synechia, or other ocular disease. The amaurosis or gutta serena is known by the total absence of light to the retina; we can distinguish this not only by the pupil being closed, but likewise the eyelids, for whether the eyelids be open or shut, all is darkness to the patient. The other complicated cases are known by viewing the eye, and eonsidering the parts anatomically

5. Synizesis spuria, is a closing of the pupil by mueus, pus, or grumous blood.

SYNOCHA. (From συνέχω, to continue.) Inflammatory fever. A species of to these are added, picking at the bedcontinued fever; characterised by increase clothes, startings of the tendons, involuned heat; pulse frequent, strong, hard; tary discharges by stool and urine, and urine high-eoloured; senses not im- hiccough, it will then certainly be fatal. On paired. This fever is so named from its the contrary, if the febrile heat abates, being attended with symptoms denoting the other symptoms moderate, and there general inflammation in the system, by is a tendency to a crisis, we may then exwhich we shall always be able readily to peet a recovery. In a few instances, this distinguish it from either the nervous or fever has been known to terminate in putrid. It makes its attack at all seasons mama. of the year, but is most prevalent in the and of a plethorie constitution. It is a species of fever almost peculiar to cold and even then, the inflammatory stage is of phus; so that synocha and typhus, blended very short duration, as it very soon as- together in a slight degree, seem to constisumes either the nervous or putrid type.

The exciting eauses are sudden transitions from heat to cold, swallawing eold liquors when the body is much heated by exercise, too free a use of vinous and -pipassions of the mind, the sudden suppression of habitual evacuations, and the sudden repulsion of eruptions. It may be doubted if this fever ever originates from and eyes, great restlessness, intense heat, cessary to produce this effect. The most

and parehed; the tongue is of a scarlet eolour at the sides, and furred with white in the centre; the urme is red and scanty; the body is costive; and there is a quickness, with a fulness and hardness in the pulse, not much affected by any pressure made on the artery. If the febrile symptoms run very high, and proper means are not used at an early period, stupor and delirium come on, the imagination becomes much disturbed and hurr ed, and the patient raves ciolently The disease usually goes through its course in about fourteen days, and terminates in a crisis, either by diaphoresis, diarrhœa, hæmorrhage from the nose, or the deposit of a eopious sediment in the urine; which crisis is usually preceded by some variation in the pulse.

Our judgment as to the termination of the disease, must be formed from the violence of the attack, and the nature of the symptoms. If the fever runs high, or continues many days with stupour or delirium, the event may be doubtful; but if

On opening those who die of an inflamspring; and it seizes persons of all ages matory fever, an effusion is often perceived and habits, but more particularly those in within the eranium, and now and then, tothe vigour of life, with strong elastic fibres, pical affections of some of the viscera are to be observed.

SYNOCHUS. (From συνεχω, to contemperate climates, being rarely, if ever tone.) . A mixed fever. A species of met with in very warm ones, except continued fever, commencing with sympamongst Europeans lately arrived; and toms of synocha and terminating in tytute this species of fever, the former being apt to preponderate at its commencement, and the latter towards its termina-

Every thing which has a tendency to ritious liquors, great intemperance, violent enervate the body, may be looked upon as passions of the mind, the sudden suppressarily a remote cause of this fever; and accordingly we find it often arising from great bodily fatigue, too great an indulgence in sensual pleasures, violent exer ion, intempersonal infection; but it is impossible peranee in drinking, and errors in diet, and for it to appear as an epidenie amongst now and then likewise from the suppressuch as are of a robust habit, from a pession of some long accustomed discharge, culiar state of the atmosphere. It comes Certain passions of the mind (such as crief, on with a sense of lassitude and inactivity, fear, anxiety, and joy.) have been enumesucceeded by vertigo, rigors, and pains rated amongst the eauses of fever, and in over the whole body, but more particular- a few instances it is probable they may ly in the head and back; which symptoms have given rise to it; but the concurrence are shortly followed by redness of the face of some other powers seems generally neusual and universal cause of this fever is creased action of the heart and arteries is the application of cold to the body; and the effect of nature to expel the morbific its morbid effects seem to depend partly upon certain circumstances of the cold it- creased secretion of bile; and others self, and partly upon certain circumstances of the person to whom it is applied.

The circumstances which seem to give the application of cold duc effect, are its degree of intensity, the length of time which it is applied, its being applied generally, or only in a current of air, its having a degree of moisture accompanying it, and its being a considerable or sudden change from heat to cold. The circumstances of persons rendering them more liable to be affected by cold, seem to be debility, induced either by great fatigue, or violent exertions, by long fasting, by the want of natural rest, by severe evacuations, by preceding disease, by errors in diet, by intemperance in drinking, by great sensuality, by too close an application to study, or giving way to grief, fear, or great anxiety, by depriving the body of a part want of taste in the mouth, slight pains in of its accustomed clothing, by exposing any one particular part of it, whilst the rest is kept of its usual warmth, or by ex- its effects after a little time become less posing it generally or suddenly to cold violent, and are alternated with flushings, when heated much beyond its usual tem- and at last, going off altogether, they are perature; these we may therefore look succeeded by great heat diffused generally upon as so many causes giving an effect to over the whole body; the face looks flushcold which it otherwise might not have ed, the skin is dry as likewise the tongue; produced. Another frequent cause of fe- universal restlessness prevails, with a viover seems to be breathing air contaminated lent pain in the head, oppression at the by the vapours arising either directly or chest, sickness at the stomach, and an originally from the body of a person labouring under the disease. A peculiar matter is supposed to generate in the body of a person affected with fever, and this 100 strekes in a minute. When the sympflorting in the atmosphere, and being ap- toms run very high, and there is a conplied to one in health, will no doubt often siderable determination of blood to the cause fever to take place in him, which head, a delirium will arise. In this fever, has induced many to suppose that this infectious matter is produced in all fevers whatever, and that they are all more or less contagious.

The effluvia arising from the human body, if long confined to one place without being diffused in the atmosphere, will, it is well known, acquire a singular virulence, and will if applied to the bodies of men, become the cause of fever. Exhalations, arising from animal or vegetable substances in a state of putrefaction, have been looked upon as another general cause of fever: marshy or moist grounds, acted upon by heat for any length of time, usually send forth exhalations which prove a neverfailing source of fever, but more particularly in warm climates. Various hypothesis have been maintained, with respect to the proximate cause of fever; some supposing it to be a lentor or viscidity prevailing in the mass of blood, and stagnating in the extreme vessels; others, that it is a noxious matter introduced into or generated in the body, and that the in- pulse becoming soft, moderate, and near,

matter; others, that it consisted in an inagain, that it is to be attributed to a spasmodic constriction of the extreme vessels on the surface of the body; which last was the docurine taught by the late Dr. Cullen.

An attack of this fever is generally mark. ed by the patient's being seized with a considerable degree of languor or sense of debility, together with a sluggishness in motion, and frequent yawning and stretch. ing; the face and extremities at the same time become pale, and the skin over the whole surface of the body appears constricted; he then perceives a sensation of cold in his back, passing from thence over his whole frame, and this sense of cold continuing to increase; tremors in the limbs and rigors of the body succeed.

With these there is a loss of appetite, the head, back, and loins, small and frequent respirations. The sense of cold and and at last, going off altogether, they are inclination to vomit. There is likewise a great thirst and costiveness, and the pulse is full and frequent, beating perhaps 90 or as well as most others, there is generally an increase of symptoms towards even-

If the disease is likely to prove fatal, either by its continuing a long time, or by the severity of its symptoms, then a start. ing of the tendons, picking at the bedclothes, involuntary discharges by urine and stool, coldness of the extremities, and hiccoughs, will be observed; where no such appearances take place, the disease

will go through its course.

As a fever once produced will go on, although its cause be entirely removed, and as the continued or fresh application of a cause of fever neither will increase that which is already produced, nor occasion a new one, there can be no certainty as to the duration of fever, and it is only by attending to certain appearances or changes, which usually take place on the approach of a crisis, that we can form any opinion or decision. The symptoms pointing out the approach of a crisis, are the its natural speed; the tongue losing its fur tendons, hiccoughs, involuntary evacua-and becoming clean, with an abatement of tions by urine and stool, and such fike thirst; the skin being covered with a gen- symptoms, point out the certain approach tle moisture, and feeling soft to the touch; of death. the secretory organs performing their secrystals of a dirty red colour, and becoming turbid on being allowed to stand any time.

Many physicians have been of opinion, that there is something in the nature of all acute diseases, except those of a putrid kind, unich usually determines them to be of a certai these terminations, when salutary, happen this fever, are an effusion within the craat certain periods of the disease rather nium, and topical affections, perhaps of than at others, unless disturbed in their progress by an improper mode of treatment, or the arising of some accidental meaning, coined by Paracelsus.) eircumstance. These periods are known by the apellation of critical days; and from the time of Hippoerates down to the present, have been pretty generally admitted. The truth of them, Dr. Thomas thinks can hardly be disputed, however they may be interrupted by various causes. A great number of phænomena shew us, that both in the sound state and the diseas- structure within the eav. ties of some ed, nature has a tendency to observe cer- joints. tain periods; for instance, the vicissitudes of sleeping and watching occurring with such regularity to every one; the acute periods that the menstrual flux observes, and the exact time of pregnancy in all viviparous animals, and many other such instances that might be adduced, all prove this law.

With respect to diseases, every one pose.) Combination. See Analysis. must have observed the definite periods which take place in regular intermit ents, eur.) The reduction of a fracture. as well those universal as topical, in the course of true inflammation, which at the fourth, or at the farthest the seven h day, is resolved, or after this period, changes into either absecss, gangrene, or schirrus, in exanthematous eruptions, which if they are favourable and regular, appear on a certain and definite day; for example, the earth; or from σίφλοι, filthy.) Lines vene-small-pox about the fourth day. All these rea. Morbus Gallicus. A genus of disease appear to be founded on immutable laws, according to which the motions of the body in health and in disease are governed.

The days on which it is supposed the termination of continued fevers princitermination of continued fevers principally happens, are the third, fifth, seventh, pearance of this disease. The novelt of ninth, eleventh, fourteenth, seventeenth, and twentieth.

ways by a regular crisis in the manner before mentioned, or from the februle matter falling on some particular parts, it excites inflammation, abscess, eruption, or destroys the patient.

Great anxiety, loss of strength, intense heat, stupor, debrium, irregularity in the pulse, twitchings in the fingers and hands, ulcers of the mouth, fauces, spots, tetters,

and ulcers of the skin, pains, swelling, and picking at the bed-clothes, startings of the

On the contrary, when the senses remain veral offices; and he wrine depositing flaky clear and distinct, the febrile heat abates, the skin is soft and moist, the pulse becomes moderate and is regular, and the urine deposits flaky erystals, we may then expect a speedy and happy termination to the disease.

> The usual appearances which are to be duration, and therefore that observed on dissection of those who die of some viscera.

SYNOVIA. (A term of no radical thros. Mucilago. An unctuous fluid secreted from certain glands in the joint in which it is contained. Its use is to lubricate the cartilaginous surfaces of the articulatory bones, and to facilitate their motions.

SYNGVIAL GLANDS. Glandulæ synoviæ. The ass mblage of a fatty fimbriated

SYNTENOSIS. (From our, with, and πενων, a tendon ) A species of articulation, where the bones are connected together by tendons.

SYNULOTICA. (Foom συνελοω, to eicatrise ) Medicines which heal wounds.

SYPHYLIS. (The ame of a shepherd, who ted the flocks of king Aleichous, who, proud of their number and beauty, insulted the sun; as a punishment for which, fable relates, that this disease was sent on in the class cachexia and order impetigines of Cullen. Towards the close of the memor, ble fifteenth century, about the year 1494 or 1495 the inhabitants of Europe its symptoms, and the wonderful rapidity with which it was propagated throughout A simple continued fever terminates al. every part of the known world, soon made it an important object of medical inquiry.

In the common language, it is said a person has syphilis or is poxed, when the venereal poison has been received into, or is diffused through the system, and there produces its peculiar effects, as caries of the bones, &c. But as long as the effects of the poison are local and confined to or near the genitals, the disorder is not called syphilis, lues venerea, nor pox; but distinguished by some particular name according to its different seat or appearance ; sueli as gonorrhea venerea, chancre

The venereal disease is always produced by a poison. Concerning the nature of this poison, we know no more than we do about that of the small-pox or any other contagion; we know only that it produces peeuliar effects. The smallest partiele of this poison is sufficient to bring on the most violent disorder over the whole body. It seems to spread and diffuse itself by a kind of fermentation and assimilation of matter; and, like other contagions, it requires some time after being applied to the human body, before it produces that effect. It is not known whether it has different degrees of acrimony and volatility, or whether it is always the same in its nature, varying only with regard to the particular part to which it is applied, or according to the different habit and constitution or particular idiosyncrasy of the person who receives the infection. We know that mercury possesses a certain and specific power of destroying the venereal virus; but we are quite uncertain whether it acts by a sedative, adstringent, or evacu- I was consulted by a gentleman about a ant quality; or if not perhaps rather by a sore throat, which I declared to be venechemical elective attraction whereby both substances uniting with one another are changed in a third, which is no more hurtful, but has some new properties en- had he any reason to believe he had tirely distinct from those which any of since received any infection: but that he them had before they were united. The had been in the East Indies, where he was variolous miasma, we know, produces its affected with a violent elap. On his return effects in about twenty or twenty-four to Europe, being to appearance in good days after the infection is received from the atmosphere, and eight or ten days if free of any such complaint ever since. By by inoculation, but the venereal virus seems to keep no particular period. At some for which he applied to me was completely times, and perhaps in particular persons, Dr. Swedianr has seen chancres arise in the space of twelve hours, nay, in a still shorter time, indeed he mentions in a few minutes, after an impure eoition; whereas, in most cases, they make their appearance only in as many days. The generality of mankind are thus easily affected by this men feel the first symptoms of a clap besween the second and fifth days after an impure-coitus; but there arc instances where they do not appear till after as many they go into infected places, and expose weeks or months. About ten years ago, themselves to inoculation or every hazard Dr. S. was consulted by a young man, who was seized with a violent discharge from the glans along with a phymosis, but without any chancres; four weeks after edition; to be infected who are seemingly of the and during all the intervals, he felt not the same habit; nay, the very same person least symptom of the disease. Some years seems to be more liable to be infected at ago, a gentleman went out from London one time than another, and those who have in seemingly perfect health, to the East been once infected seem to be more liable

Indies; but on his arrival in that hot climate, after a voyage of four months a violent clap broke out before he went on shore, though he could have received no infection during the voyage, as there was not a woman on board. There are instances which render it probable that the virus may lie four, five, or six weeks, and perhaps longer, on the surface of the genitals before it is absorbed; and were it not then to produce a shanker, might probably not be absorbed at all. We see daily examples, where common women communieate the infection to different men in the space of several weeks, while they themselves have not the least symptom of syphilis local or universal, the poison lying all that time in the vagina harmless, and generally without being absorbed. How long the venereal virus may lurk in the body itself, after it has been absorbed into the mass of blood, before it produces any sensible effect, is a matter of equal uncertainty. There is scaree a practitioner who has not observed instances of its remaining harmless for weeks or even months in the body. Dr. Swediaur had a case, where, after lying dormant for half a year, it broke out with unequivocal symptoms. But the following instance, if to be depended upon, is still more extraordinary.

Some years ago, says the above writer, real. My patient was astonished; and assured me that for nine years past he had not had the least venereal complaint, nor health, he married, and continued perfectly a mercurial course, however, the complaint removed. With regard to its effects, the venereal poison follows no constant rule: for though, in general, it affects first the throat, where it produces ulcerations, while in others it exerts its virulence on the skin or bones. Whilst the greatest part of poison, there are some few who seem to be altogether unsusceptible of the infection with the variolous contagion, though by which the disease is generally communicated.

Some persons are more liable than others

SYPHILIS. 791

to catch the infection a second time, than tals are sound; or, whether a child is ever those who never were infected before with affected with venereal symptoms in the the disease. The climate, season, age, interus of an infected mother. Such infectstate of health, idiosyncrasy, are, perhaps, ed infants as came under the observation as in other diseases, the necessary p edis- of Dr. Swediaur or of his friends, whose posing causes. The same difference is ob- practice afforded them frequent opportuservable in the progress made by the dis- nities of seeing new-born infants, seemed ease after the patient is infected. In some others it advances with the umost rapidity, and speeddy produces the most terrible symptoms. Whether the venereal poison can be absorbed into the system, wishout a previous excoriation, or ulceration of the genitals, or some other parts of the surface of the body, is still a matter of doubt. Several cases, however, have occurred which render it highly probable, if not certain, that the poison really is now and then absorbed, without any previous excoriation or ulceration whatsoever, and thus produces buboes and other venereal

symptoms in the body.

It has been asserted by the earliest and even by some late writers, that it may be caught by lying in the same bed or living in the same room with or after an infected person. What may have been the case at the commencement of the disease, cannot be said, but the most accurate observations and experiments which have been made upon the subject, do not confirm this to be the case in our times. Nor are nurses infected in the Lock Hospital, where they live night and day with patients in all stages of the distemper. The fact seems to be, that patients in our times are apt to impose upon themselves or upon physicians and surgeons, with regard to this matter; and the above opinion easily gains ground among the vulgar, especially in countries where people are more influenced by prejudices, superstition, servile situation in life, or other eirenmstances. Hence, we sometimes hear the most ridiculous accounts given in those countries by friars and common soldiers, of the manner by which they came to this disorder; such as piles, gravel, colics, contusions, fevers, little-houses, lying in suspected heds, or lying in bed with a suspected person, retention of the semen, coition with a wowan in menstruation, the use of cider, bad wine or beer, &c.

Another question undecided is, whether the venereal poison ever infects any fluid of our body besides the mucous and lymphatic system Does the venereal poison in an infected woman ever affect the milk, and consequently can the infection be conveyed to the infant by the milk alone, without any venereal ulcer on or about the nipples? It is equally a matter of uncertainty whether the venereal disease is ever conveyed of venereal ulcers in the nostrils, eye-lids, from an injected father or mother, by and lips of persons who had touched their

rather to militate against the opinion. the progress is slow, and the disease appears scarce to gain any ground, while in been able to observe ulcerations or other symptoms of a venereal kind upon newborn children; and such as make their appearance, four, six, or eight, or more days afterw rds, on the genitals, anus, lps, month, &c. may rather be supposed to arise by infection during the passage from ulcers in the vagina of the mother, the skin of the infant being then nearly in as tender a state as the glans penis, or the labia; and this perhaps at the time when an absorption of the venereal poison might easier take place without a previous excoriation, or ulceration of the skin. All the ways, therefore, by which we see, in our days, the venereal poison communicated from an unhealthy to an healthy person may be reduced to the following heads:

1. By the coition of an healthy person with another who is infected with venereal

symptoms of the genitals.

2. By the coition of an healthy person with another apparently healthy, in whose genitals the poison lies concealed, without having yet produced any bad symptom. Thus a woman who has perhaps received the infection from a man two or three days before, may during that time infect, and often does infect the man or men who have to do with her afterwards, without having any symptoms of the disease visible upon herself; and vice versa, a man may infect a woman in the same manner. Such instances ocear in practice every

3. By sucking; in this case the nipples of the wet nurse may be infected by venereal ulcers in the mouth of the child: or vice versd, the nipples of the nurse being infected, will occasion venereal ulcers in the child's nose, mouth, or lips. It is uncertian as mentioned above, whether the venereal poison was ever propagated by means of the milk from the breast.

4. By exposing to the contact of venereal poison any part of the surface of the body, by kissing, touching, &c. especially if the parts so exposed have been previously excoriated, wounded, or ulcerated by any cause whatever. In this manner we frequently see venereal ulcers arise in the scrutum and thighs; and there are some well attested instances where the infection took place in the fingers of midwives or surgeons. Several instances are recorded coition, to the fatus, provided their genia own gentals, or those of others, affected and then rubbed their nostrils, &c. with the fingers, without previously washing the hands. There was a few years ago in London, a melancholy example of a young lady, who, after having drawn a decayed tooth, and replaced it w th one taken im- after infection is very various, being most mediately from a young woman apparently in perfect health, was soon after affected cases not till after the expiration of as with an ulcer in the mouth. The sore ma nifested symptoms of a venereal nature; but such was its obstinacy, that it resisted the most powerful mercurial remedies, terminating at last in a caries of the m. xilla with a most shocking erosion of the mouth and face, by which the unhappy patient was destroyed. During all this, however, we are informed that not the smallest venereal symptom was perceived in the woman from whom the sound tooth was procured.

5. By wounding any part of the body with a lancet or knife infected with the venereal virus In this instance there is a similarity between the venereal poison and that of the small-pox. There are several examples of the latter being produced by bleeding with a lancet which had been previously employed for the purpose of inoculation, or of opening variolous pustules, without being properly cleaned afterwards. In Moravia, in the year 1577, a number of persons who assembled in a house for bathing, had themselves, according to the custom of that time, scarified by the barber, were all of them infected with the venereal disease, and treated accordingly. Krato, the physician, and Jordan, who gave a description of this distemper, are both of the opinion that it was communicated by means of the scarifying instrument. And Van Swieten relates several instances where the lues was communicated by a similar carelessness in cleaning the instrument used in bleeding or sca-

The venereal poison applied to the urethra and vagina produce a clap. See Gonorrhaa. Coming into contact with other parts it produces a chancre or bubo and constitutional symptoms. Chancre is the primary and immediate consequence of inoculation with true venercal matter in any of the ways which have been mentioned, and may arise in any part of the human body: but it generally shews itself in the pudenda, because the infecting medium is there first taken up in the one sex, and communicated by contact to the other. It is not, however, peculiar to these parts, for whenever the same kind of fluid is applied to a scratch on the hand, finger, lip or become scirrhous. The following are the nipple, the same consequence will follow. characteristics of a venereal bubo. There can be no doubt but that the slightest swelling is usually confined to one gland, abrasion possible, or breach of the cuticle, the colour of the skin where inflammation is sufficient to give a speedy admission to prevails is of a florid red, the pain is very this destructive poison. A chancre makes acute, the progress from inflammation to

at the time with local venereal complaints, its appearance either with a slight inflammation which afterwards ulcerates, or there arises a small pimple or pustule filled with a transparent fluid, which soon breaks and forms into a spreading ulcer. The period at which it makes its appearance commonly in five or six days, but in some many weeks. There is both a local and general predisposition to chancres: Jews and Mahomedans, from the constant exposure of the glans and loss of the prepuce. have the cuticle of the glans penis of much firmer texture than those who have not been circumcised; and they are from this circumstance, much less subject to chancres than the rest of mankind. For the same reason they who, from the shortness of the prepuce, generally keep the glans uncovered, are neither so liable to the disease as those who have long narrow preputia; for persons thus formed constantly keep the surface of the glans and prepuce moist and tender, and almost at every co. habitation are liable to abrasions and to excoriations.

There is an intermediate state of the venereal disease between a local and constitutional affection, which arises from the absorption of venereal matter from some surface to which it has been applied. The glands situated nearest the parts thus affected are apt to become swelled and inflamed, and so as to give rise to what is termed bubo; and the parts of generation usually coming first in contact with the matter, so the glands in the groin generally afford this particular symptom. In most cases the venereal virus is absorbed from a chancre or an ulcer in the urethra; but instances have occurred where a bubo has arose without either gonorrhæa or any kind of ulceration, and where the matter appears to have been absorbed, without any erosion of the skin or mucous membrane.

A bubo comes on with a pain in the groin, accompanied with some degree of hardness and swelling, and is at first about the size of a kidney bean, but continuing to increase, it at length becomes as large as an egg, occasions the person to experience some difficulty in walking, and is attended with a pulsation and throbbing in the tumour, and a great redness of the skin. In some cases the suppuration is quickly completed, in others it goes on very slow, and in others again the inflammatory appearances go off without any formation of pus. In a few instances the glands have been known to suppuration and ulceration is generally very rapid, the suppuration is large in proportion to the size of the gland, and there

is only one abscess.

A bubo is never attended with danger, where the inflamed gland proceeds on regularly to supportation, but in particular cases it acquires an indolence after coming to a certain length, arising from a scrophulous taint, or by being combined with erysipelas it terminates in gangrene and occasions a great loss of substance. This termination is, however, more frequently met with in hospitals than in private practice, and may partly be attributed to the contaminated state of the air of the wards wherein venereal patients are lodged.

A constitutional taint is the third form under which it has been mentioned, that the venereal poison is apt to shew itself, and which always arises in consequence of the master being absorbed and carried into the circulating mass of fluids The absorption of it may, however, take place

in three ways

1st. It may be carried into the circulation, without producing any evident local effect on the part to which it was first applied

2ndly. It may take place in consequence of some local affection, such as either gonorthes, chancre, or boba: And,

3dly It may ensue from an applicationof the matter to a common sore or wound, similar to what happens in inoculating for the small-pox

The most general way, however, in which a constitutional tains is produced, is hy an absorption of the matter, either from

a chancre or a onbo.

When venereal matter gets into the system, some symptoms of it may often be observed in the course of six or eight weeks, or probably sooner: but in some cases, it will continue in the circulating mass of fluids for many months before any visible signs of its effects are produced The sys em being completely contaminated, it then occasions many local effects in different parts of the body, and shows itself under a variety of forms, many of which put on the appearance of a distinct disease. We may presume that this variety depends wholly on the difference of constitution, the different kind of parts affected, and the different state these parts were in at the time the matter or poison was applied.

The first symptoms usually shew themselves on the skin and in the month or When on the skin, reddish and brownish spots appear here and there on the surface, and eruptions of a copper colour are dispersed over different parts of the body, on the top of which there soon forms a thick scurf or scale. This scurf falls off after a short time and is succeeded by another, and the same enlar ements and indurations of the lym-

happening several times, and at length casting off dee; scabs, an older is formed which discharges an acrid fæ'id matter. When the matter is secreted in the glands of the throat and mouth, the tongot will often be affected so as to occasion a thickness of speech, and the tonsils, palate, and uvala will become ulcerated so as to produce a soreness and difficulty of swallowing, and likewise a hoarseness in the voice. In the venereal ulcer of the tonsil a portion of it seems as if it was dug out; it is, moreover, very foul, and has a thick white matter adherm to it, which cannot be washed off By these characteristic marks it may, in general, readily be distinguish. ed from any other species of afceration in these parts.

If the disease affects the eyes, obstinate inflammation, and sometimes ulceration

will also attack these organs.

The matter sometimes falls on deep seated parts, such as the tendons, ligaments, and perios'eum, and occasions hard, painful swellings to arise, known by the name of nodes

When the disease is suffered to take its own course, and no counteracted by proper remedies, the patient will in the course of time, he afflicted with severe pains, but more particularly in the night time; his countenance will become sallow, his hair will fall off, he will lose his appetite, strength and flesh, his rest will be much disturbed by night, and a small lever of the heetic kind will wise. The alcers in the mouth and throat being likewis s ffered to spread, and to occasion a ciries of the bones of the palate, an opening will be made from the mouth to the nos, and the cartilages and bones of the n s: be ng at leng h corroded away, this will sink on a level with the face. Some consistations will bear up for a considerable time against the disease, whilst others again will soon sink under a general weakness and irritation produced by it. If the disorder is recent, and the constitution not impaired by other diseases, a perfect cure may e sily be effected; but where it is of long standing, and accompanied with the symptoms of irritation which have been nentioned, the cure will prove tedious, and in many cases uncertain, as the constitution and strength of the patient may not admit of his going through a course of medicine sufficient to des roy the poison, or his health may be in such a state, as that only a very small quantity of mercury can be administered even at considerable inter-

The general appearances to be observed on dissection of those who die of lies, are. caries of the bones, but more particularly those of the cranium, often communicating ulceration to the brain itself, together with

phatic glands, scirrhus of several of the organs, particularly the liver and lungs, and exastoses of many of the hardest bones.

TEETH.

parts; viz. its body, or that part which ances still subsisting, with this addition, appears above the gums; and its fangs or that all the parts of the teeth which were root, which is fixed into the socket. The formed after leaving off the madder will boundary between these two, close to the be write. This experiment proves that a edge of the gum, where there is usually a small circular depression, is called the neck of the tooth. The teeth of each jaw are commonly divided into three classes; but before each of these is treated of in particular, it will be right to say some-

thing of their general structure. Every tooth is composed of its cortex or enamel, and its internal bony substance. The enamel, or as it is sometimes called, the vitreous part of the tooth, is a very hard and compact substance, of a white colour, and peculiar to the teeth. It is found only upon the body of the tooth, covering the outside of the bony or internal substance. When broken it appears fibrous or striated; and all the striæ are directed from the circumference to the centre of the tooth. This enamel is thickest on the grinding surface, and on the cutting edges or points of the teeth, becoming , radually thinner as it approaches the neck, where it terminates insensi-Some writers have described it as being vascular, but it is certain that no injection will ever reach this substance; that it receives no tinge from madder; and that it affords no appearance of a circulation of fluids The bony part of a tooth resembles other bones in its structure, but is much harder than the most compact part of bones in general It composes the inner part of the body and neek, and the whole of the root of the tooth. This part of a too h, when completely and there does not appear to be any doubt formed, does not, like the other bones, receive a tinge from madder, nor do the minutest injections penetrate into it's substance, although many writers have asserted the contrary. Mr. Hunter has been therefore induced to deny its being vascular, although he is aware that the teeth, like other bones, are liable to swellings, especially as we find them invested with a and that they are found anchylosed with periosteum. 3dly, It is a curious fact, their sockets. that both these may be original forma- that, in eases of phthisis pulmonalis, the tions; and, as the most convincing proof teeth become of a milky whiteness, and in of their not being vascular, he reasons from the analogy between them and other bones. He observes, for instance, that in that such parts as were formed while the of a red colour; whereas, in other bones, the hardest parts are susceptible of the dye, though more slowly than the parts which are growing. Again, he tells us, that if you leave off feeding the animal

Each tooth may be divided into two you kill it, you will find the above appeartooth once tinged does not lose its colour: whereas other bones do (though very slowly) return again to their natural appear. ance: and, as the dye in this case must be taken into the habit by absorbents, he is led to suspect that the teeth are without absorbents as well as other vessels. These arguments are very ingenious, but they are far from being satisfactory. The facts adduced by Mr. Hunter are capable of a different explanation from that which he has given them; and when other facts are added relative to the same subject, it will appear that this bony part of a tooth has a circulation through its substance, and even lymphanes, although, from the hardness of its structure, we are unable to demonstrate its vessels. The facts which may be adduced are, 1st. We find that a tooth recently drawn and transplanted into another socket, becomes as firmly fixed after a certain time, and preserves the same colour as the rest of the set; whereas a cooth hat has been long drawn before it is transplanted, will never become fixed Mr. Hunter, indeed, is aware of this objection, and refers the success of the transplanta. tion, in the first instance, to the living principle possessed by the tooth, and which he thinks may exist independent of a circula ion. But however applicable such a doctrine may be to zoophytes, it is suspeeted that it will not hold good in man, and others of the more perfect animals; but that, in the case of a transplanted tooth, there is a real union by vessels. 2dly. The swellings of the fangs of a tooth, which in many instances are known to be the effects of disease, and which are analogous to the swelling of other hones, are a clear proof of a similarity of structure, He supposes, however, though as yet perhaps not generally known, some degree, transparent; does not this prove them to have absorbents? Each tooth has an inner cavity, which,

a young animal that has been fed with beginning by a small opening at the point madder, the parts of the teeth which were of the fang, becomes larger, and termi-formed before it was put on madder diet nates in the body of the tooth. This will appear of their natural colour, but cavity is supplied with blood-vessels and nerves, which pass through the small animal was taking the madder, will be hold in the root. In old people this hole sometimes closes, and the tooth becomes then insensible.

The teeth are invested with a periosteum from their fangs to a little beyond their bony sockets, where it is attached to the with madder a considerable time before gums. This membrane seems to be com-

TEETH: 801

mon to the tooth which it encloses, and to have in general only one root, and the body the sockets which it lines. The eeth are of the tooth terminates in two points, of likewise secured in their sockets by a red which the anterior one is the highest, so that substance called the gums, which every the tooth has in some measure the appearwhere covers the alveolar processes, and has as many perforations as there are teeth. The gums are exceedingly vascular, and have something like eartilaginous hardness and elasticity, but do not seem to have much sensibility. The gums of infants, which perform the offices of teeth have a hard ridge extending through their whole length; but in old people, who have lost their teeth, this ridge is wanting. The three classes into which the teeth are commonly divided, are incisores, canini, and molares or grinders.

The incisores are the four teeth in the fore part of the jaws; they derive their name from their use in dividing and cutting the food in the manner of a wedge, and have each of them two surfaces, which meet in a sharp edge. Of these surfaces, the anterior one is convex, and the postejaw they are usually broader and thicker, especially the two first, than those of the

by being placed a little obliquely.

most perfectly earnivorous.

ance of one of the canini The two grinders beyond these, on each side, are much larger. Their body forms almost a square with rounded angles; and their grinding surface has commonly five points or protuberances, two of which are on the inner, and three on the outer part of the tooth. The last grinder is shorter and smaller than the rest, and, from its coming through the gums later than the rest, and sometimes not appearing till late in life, is called dens sapientiæ. The variation in the number of teeth usually depends on these dentes sapientiæ.

Having thus described the appearance of the teeth in the adult; the manner of their formation and growth in the fœtus is next to be considered. We shall find that the alveolar process, which begins to be formed at a very early period, appears about the rior one somewhat concave. In the upper fourth month, only as a shallow longitudinal groove, divided by slight ridges into a number of intermediate depressions, under jaw, over which they generally fall which are to be the future alveoli or sockets. These depressions are at first filled The estini or cuspidati are the longest of all the teeth, deriving their name from their vascular membrane; and these pulpy subresemblance to a dog's tusk. There is stances are the rudiments of the teeth. As one of these teeth on each side of the incisores, so that there are two in each jaw, processes become gradually more com-They are the longest of all the teeth. Their fangs differ from that of the incisores only first begins to harden; the ossification proin being much larger, and their shape may be easily described to be that of an incisor with its edge worn off, so as to end in a formed. Thus, in the incisores and caagreemy point instead of a thin edge. The point is to be found. narrow point instead of a thin edge. The nuni, it begins from one point; in the bicanini not being calculated for dividing cuspides, from two points, corresponding like the incisores, or for grinding, seem to with the future shape of those teeth; and be intended for laying hold of substances. in the molares from four or five points As Mr. Hunter remarks of these teeth, that the ossification advances, the whole of the we may trace in them a similarity in shape, pulp is gradually covered with bone, exsituation, and use, from the most imperfect cepting its under surface, and then the carnivorous animal which we believe to be fang begins to be formed. Soon after the the human species, to the lion, which is the formation of this bony part, the tooth begins to be incrusted with its enamel; but The molarcs, or grinders, of which in what manner this is deposited we are there are ton in each jaw, are so called, as yet unable to explain.-Perhaps the because from their size and figure they are vascular membrane, which encloses the calculated for grinding the food. The ea- pulp, may serve to secrete it. It gradunini and incisores have only one fang, but ally crystallizes upon the surface of the the three last grinders in the under jaw bony part, and continues to increase in have constantly two fangs, and the same thickness, especially at the points and teeth in the upper jaw three fangs. TEETH.

begins from different parts of the pulp at pletely filled with twenty teeth, as they one and the same time In this manner are afterwards with thirty-two. Hence, in are formed the incisores, the canini, and children the face is flatter and rounder than two motares on each side, making in the whole twenty teeth, in both jaws, which are sufficient for the purposes of manducation early in life. As the fangs of the teeth are formed, their upper part is gradually pushed upwards, till at length, about the seventh, eighth, or ninth mouth after birth, the incisores, which are the first formed, begin to pass through the gum. The first that appears is generally in the lower jaw. The canini and molares not being formed so soon as the incisores, do not appear till about the twentieth or twenty-fourth month. Some times one of the canini, but more frequently one of the molares appears first.

The danger to which children are exposed, during the time of dentition, arises from the pressure of the teeth in the gum, so as to irritate it, and excite pain and inflammation. The effect of this irritation is, that the gum wastes, and becomes gradually thinner at this part, till at length the tooth protrudes. In such cases therefore we may, with great propriety, assist nature by cutting the gum. These twenty teeth are called temporary, or milk teeth, because they are all shed between the age of seven and fourteen, and are supplied by others of a firmer texture, with large fangs, which remain till hey become affected by disease, or fall out in old age, and are therefore called the permanent, or adult teeth. The rudiments of these adult teeth begin to be formed at different peri-The pulp of the first adult incisor, and of the first adult grinder, may be perceived in a foctus of seven or eight months, and the ossification begins in them about six months after birth. Soon after birth the second incisor, and canine tooth on each side, begin to be formed. About the fifth or sixth year the first becaspis and about the seventh the second bicuspis begins to ossify. These bicuspides are destined to replace the temporary grinders. All these permanent teeth are formed in a distinct set of alveoli; so that it is not by the growing of one tooth under another in the same socket, that the uppermost tooth is gradually pushed out, as is commonly imagined; but the temporary teeth, and those which are to succeed them, being placed in separate alveol, the upper sockets gradually disappear, as the under ones increase in size, till at length the teeth they contain, having no longer any support, consequently fall out. But, besides these twenty teeth, which succeed the temporary ones, there are twelve others to be added to make up the number thirty-two. These mastication. And here we cannot help twelve are three grinders on each side in both jaws; and in order to make room for of the human teeth, which fits us for such a this addition, we find the jaws grow as the variety of food, and which, when compared

in adults The first adult grinder usually passes through the g.m about the twelfth year; the second, which begins to be formed in the sixth or seventh year, cuts the gum about the seventeenth eighteenth; and the third or dens sapien. tiz, which begins to be formed about the twelfth year, passes through the gum between the age of twenty and thirty. The dentes sapientiæ have, in some instances. been cut at the age of forty, fifty, sixty, and even eighty years; and it sometimes happens that they do not appear at all. Sometimes likewise it happens, that a third set of teeth appear about the age of sixty or seventy. Dermebroeck tells us that he himself, at the age of fifty-six, had a fresh canine tooth in the place of one he had lost several years before; M. du Fay saw two incisores and two canini cut the gum in a man aged eighty-four; Mr. Hunter has seen two fore-teeth shoot up in the lower jaw of a very old person; and an account was lately published of a man who had a complete set at the age of sixty. Other instances of the same kind are to be met with in authors. The circumstance is curious, and from the time of life at which it takes place, and the return of the catamenia, which sometimes happens to women at the same age, it has been very ingeniously supposed, that there is some effort in nature to renew the body at that period. The teeth are subject to a variety of ac-

Sometimes the gums become so cidents. affected as to occasion them to fall out, and the teeth themselves are frequently rendered carious by causes which have not hitherto been satisfactorily explained. The disease usually begins on that side of the tooth which is not exposed to pressure, and gradually advances till an opening is made into the cavity: as soon as the cavity is exposed, the tooth becomes liable to considerable pain, from the air coming into contact with the nerve. Besides these accidental means by which the teeth are occasionally affected, old age seldom fails to bring with it sure and n tural causes for their removal. The alveoli fill up, and the teeth consequently fall out. The gums then no longer meet in the fore part of the mouth, the chin projects forwards, and the face being rendered much shorter, the whole physiognomy appears considerably altered. . Having thus described the formation, structure, growth, and decay of the teeth, it remains to speak of their uses; the chief of which we know to be in observing the great variety in the structure teeth grow, so that they appear as com- with the teeth given to other animals, may

803

an some measure enable us to explain the vision most generally received is into the nature of the aliment for which man is intended by Nature. Thus, in ruminate animals, we find incisores only in the lower jaw, for cutting the grass, and molares for grinding it; in graminivorous animals, we see molares alone; and in carnivorous animals, canine teeth for catching at their prey, and incisores and molares for cutting and dividing it. But, as man is not designed to catch and kill his prey with his teeth, we observe that our canini are shaped differently from the fangs of beasts of prey, in whom we find them either longer than the rest of the teeth, or curved. The incisores likewise are sharper in those animals than in man. Nor are the molares in the human subject similar to the molares of carnivorous animals; they are flatter in man than in these animals; and, in the latter, we likewise find them sharper at the edges, more calculated to cut and tear the food, and, by their greater strength, capable of breaking the bones of animals. From these circumstances, therefore, we may consider man as partaking of the nature of these different classes; as approaching more to the carnivorous than to the herbivorous tribe of animals; but upon the whole, formed for a mixed aliment, and fitted equally to live upon flesh and upon vegetables. Those philosophers, therefore, who would confine a man wholly to a vegetable food, do not seem to have studied nature. As the molares are the last teeth that are formed, so they are usually the first that fall out; this would seem to prove, that we require the same kind of aliment in old age as in infancy. Besides the use of the teeth in mustication, they likewise serve a secondary purpose, by assisting in the articulation of the voice.

Teething. See Dentition and Teeth TEGULA HIHEHNICA. See Lapis Hiberni-

TEGUMENTS, COMMON. Under this term anatomists comprehend the cuticle, rete mucosum, skin, and adipose membrane, as being the covering to every part of the body except the nails. See Skin

A web of cloth. The cellular membrane is so called from its likeness to

a fine web.

TELA CELLULOSA. See Cellular mem-

TELEPHICM. (Because it heals old ulcers, such as that of Telephus, made by Ulysses.) See Fabu crassu.

TELLURIUM. A very scarce metal of a tin white colour, and a high metallic lustre, found in nature alloyed with gold, silver, and lead, in the aurum paradoxicum and sylvanite.

TEMPERAMENTUM. (From tempe-To, to mix together.) The peculiar con- affords a pas age to the portio dura of the stitution of the humours. Temperaments and to yor seventh pair of nerves 5 Be-

sanguinous, phlegmatic, choleric, and melancholic.

TEMPLE. The lateral and flat parts of the head above the ears.

TEMPORALIS ARTERIA. The 'emporal artery. A branch of the external caroud, which runs on the temples and give off the frontal artery.

TEMPORAL BONES. Ossa tempora-Ossa temporum These two bones, which are situated one on each side of the head, are of a very irregular figure. They are usually divided into two parts, one of which from the manner of its connexion with the neighbouring bones, is called os squamosum, and the other os petrosum, from its irregularity and hardness.

In both these parts there are processes and cavities to be described Externally there are three processes; one anterior, called zygomatic process, which is stretched forwards to join with the os malæ, and thus forms the bony jugum under which the temporal muscle passes; one posterior, called the mastoid or mamillary process, from its resemblance to a nipple; and one inferior, called the styloid process, from its shape, which is said to resemble that of the ancient stylus scriptorius. In young subjects this process is united with the bone by an intermediate cartilage, which sometimes, even in adults, is not completely ossified Three muscles have their origin from this process, and borrow half of their names from it, viz stylo-glossus, stylo-hyordeus, and stylo-pharyngeus. Round the root of this process there is a part cular rising of the os petrosum, which some writers describe as a process, and, from its appearance with the s yloid, have named it vaginalis, others describe the semi-circular ridge of the meatus anditorius externus as a fifth process, to which they give the name of auditory. The depressions and cavities arc, 1 A large fossa, which serves for the articulation of the lower jaw; it is situated between the zygomatic auditory, and vaginal processes, and is separated in its middle by a fissure into which the ligament that secures the articulation of the lower jaw with this bone is fixed. The fore part of this cavity, which receives the condyle of the jaw, is covered with car-ilage; the back part only with the perios enni. 2 A long ossa behind the mustoid process, where the digastrie muscle has its origin. 3 The meatus auditorius externus, the name given it a large funnel-like canal that leads to the organ of heating. 4. The style masteid hole, so called from its situation between the s ylood and mastord processes It is I kewise called the aqueduct of Fallopius, and have been variously distinguished: the di- low and on the fore part of the last foramen we observe part of the jugular fossa, nous substance; there is no appearance a thimble-like cavity, in which the begin- either of the mastoid or styloid processes. ning of the internal jugular vein is lodged, and, instead of a long funnel-like meatus 6. Before, and a little above this fossa is auditorius externus, there is only a smooth the orifice of a foramen, through which bony ring, within which the membrana pass the internal carotid artery and two filaments of the intercostal nerve. This conduit runs first upward and then forward, forming a kind of elbow, and terminates at the end of the os petrosum. 7. At this part of the ossa temporum we observe the orifice of a canal which runs outwards and backwards in an horizontal di rection, till it terminates in the cavity of the ear called tympanum. This canal, which in the recent subject is continued from the ear to the mouth, is called the culus.) Arcardi-temporo-maxillaire of Du-Eustachian tube. We shall speak of it more mas. This muscle, which Winslow has particularly hereafter. 8 A small hole behind the mastoid process, which serves for the transmission of a vein to the lateral sinus. But this, like other foraming in the tien of the temporal bone; from the lower skull that serve only for the transmission of and lateral part of the os frontis; from vessels, is neither uniform in its situation, the posterior surface of the os malz; from nor to be met with in every subject. The internal surface of these bones may easily be divided into three parts. The first, up- lower part of this process. This latter permost and largest, is the squamous part, portion, however, is often common to this which is slightly concave from the impression of the brain. Its semicircular edges is sloping, so that the external lamella of fibres converge, so as to form a strong the bone advances farther than the internal, and thus rests more securely on the parietal jugum, and is inserted into the coronoid bones. The second and middlemost, which process of the lower jaw, to which it adis the petrous part of the bone, forms a heres on every side, but more particuhard, craggy protuberance, nearly of a triangular shape. On its posterior side we observe a large foramen, which is the meatus auditories internus; it receives the double nerve of the seventh pair, viz. the por- ously described as a part of the aponeurotio dura and portio modis of that pair. About the middle of its anterior surface is a small for men, which opens into the aque- circumference of the origin of the muscle, duct of Failopius, and receives a twig of the portio dura of the seventh pair of the ridge where the zygomatic process nerves. This foramen having been first described by Fallopins, and by him named hiatus, is sometimes called hiatus Fallopii. itself, and anteriorly to the smalz. Besides these, we observe other smaller fascia serves as a defence to the muscle, holes for the transmission of blood-vessels and likewise gives origin to some of its fleshy and herves. rance is the third part, which, from its muscle is to draw the lower jaw upwards, shape and connexion with the os occipitis by means of the lambdoidal suture, may be called the lambdoidal angle of the temporal bone. It is concave from the impression of the brain; it helps to form the posterior and inferior fossæ of the skull, and has a considerable furrow, in which is lodged part of the lateral sinus. The temporal bones differ a little in their structure from the other bones of the cranium. At their upper parts they are very thin, and tendo. almost without diploë, but below they have great strength and thickness. In the fætus, the thin upper part, and the lower craggy part, are separated by a cartilagi-

tympani is fastened. Within the petrous part of these bones there are several cavities, processes, and bones, which belong altogether to the ear, do not enter into the formation of the cranium, and are described under the article Ear. The ossa temporum are connected by suture with the ossa parietalia, the os occipitis, the ossa malarum, and the os sphenoides, and are articulated with the lower jaw,

TEMPORALIS (Temporalis sc. mus. named the crotophyte, arises fleshy from the lower, lateral, and anterior part of the parietal bone; from all the squamous porall the temporal process of the sphenoid bone; and sometimes from a ridge at the muscle and the pterygoideus externus. It is of a semicircular shape, and its radiated middle tendon, which passes under the larly at its fore part, where the insertion is continued down to the body of the bone. This muscle is covered by a pretty strong fascia, which some writers have erronesis of the occipito-frontalis. This fascia adheres to the bones, round the whole and, descerding over it, is fixed below to begins, just above the meatus auditorius; to the upper edge of the zygomatic process Below this craggy protube- fibres. The principal use of the temporal as in the action of biting; and as it passes a little forwards to its insertion, it may at the same time pull the condyle a little backwards, though not so much as it would have done if its fibres had passed in a direct line from their origin to their insertion, because the posterior and lower part of the muscle passes over the root of the zygomatic process, as over a pulley.

Achillie See TENDO ACHILLIS.

TENDON. (Tendo, from tendo, to stretch.) The white and glistening extremity of a muscle. See Muscle.

(From Telva, to cen-TENESMUS.

stringe; so called from the perception of a continual constriction or bou d state of the part.) A continual inclination to go to stool, without a discharge.

TENSOR (From tende, to stretch.)

to which it is fixed.

TENSOR PALATI. See Circumflexus.

TENSOR TYMPANI. Internus auris of Diu les and Cowper Internus mallei of Winslow, and salpingo mulleen of Dumas A muscle of the ear, which pulls the malleus and the membrane of the tympan m towards the petreous portion of the temporal bone, by which the membrana tympani is made more concave and 'ense.

TENSOR VAGINÆ FEMORIS. Fas. Membranosus of Douglas branus vel fuscia lata of Cowper, and Ilio apmeurosi femoral of Dum s. Musculus aponeurosis, vel fascia lata of Winslow. A muscl, situated on the outside of the thigh, which stretches the membranous fascia of the thigh, assists in the abduction of the thigh, and somewhat in its rotation in-It arises by a narrow, tendinous, and fleshy beginning from the external part of the anterior, superior, spinous process of the ilium, and is inserted a little below the great trochanter into the membranous fascia.

TENT. A roll of lint for dilating open-

TENTORIUM. A process of the dura mater, separating the cerebrum from the cerebellum It extends from the internal horizontal spine of the occipital bone, directly forwards to the sella turcica of the sphænoid bone.

TEREBELLA. (Dim. of terebrn, a piercer or gamblet.) A trepan or instrument for sawing out circular portions of the skull.

A trephine.

TEREBINTHINA. (From Tegesiveos, the turpentine tree.) Turpentine, the

produce of pine-trees.

TEREBINTHINA ARGENTAROTEN-Strasburg turpentine. This species is generally more transparent and less tenacious than either the Venice or Chio turpentines. It is of a yellowish brown colour, and of a more agreeable smell than any of the turpentines, except the Chio. It is extracted in several parts of Germany, from the red and silver fir, by cutting out, successively, narrow strips of the back In some places a resinous price is codected from under the bark called Cachrym ab egna, and oleum abietinum

TEREBINTHINA CANADENSIS. Canada turpentine. A production of the pinus balsamen See Balsamum Canadense.

TEREBINTHINA CHIA. Cyprus turpentine. The resin obtained from the pistacia terebinthus. See Chio turpentine.

TEREBINTHINA COMMUNIS. See Terebinthina vulgaris.

TEREBINTHINA CYPRIA. See Chio turpen-

TEREBINTHINA VENETA. turpen ine; so called because we are supplied with it from the V netians. A muscle whose office is to extend the part species of turpentine issues spontaneously through the bark of the Pinus lang; folis fasciculatis mollibus obtusiusculis bracteis ex tra squamas strobilorum exuntibus. Hort. It is usually thenner than any of the other sorts; of a clear whitish or pole yellowish colour; a hot, pungent, bitterish, disagreeable taste; and a strong smell, without any thing of the atomatic flavour of the chian kind For its virtues see Turpentines

TEREBINTHINA VULGARIS. Common turpentine. The liquid resin of the pints sylvestris. See Turpentine.

TEREBUNTHINE OLEUM. The oil distilled from the liquid resin of the pinus

TERES. Round, smooth. 1. The name

of some muscles and ligaments.

2. The name of the ascaris lumbricoides, or round worm, which infests the intestines. Teres ligamentum. The ligament at the bottom of the socket of the hip joint,

TERES MAJOR TERES MAJOR (Teres sc. Musculus major. Teres, round, smooth) Riolanus, who was the first that distinguished this and the other muscles of the scapula by particular appellations, gave the name of teres to this and the following muscle, on account of their long and round shape. Anguliscapulo. Humeral, of Damas. This muscle, which is longer and thicker than the teres minur, is situated along the inferior costa of the scapula, and is in part covered by the deltoides.

It arises fleshy from the outer surface of the inferior angle of the scapula, (where it covers some part of the infra spinacus and teres minor, with both which its fibres intermix,) and likewise from the lower and posterior half of the inferior costa of the scapula. Ascending obliquely towards the os humeri, it passes under the long head of the triceps brachii, and then becomes thinner and flatter to form a thin tendon of about an inch in breadth, and somewhat more in length, which runs immediately behind that of the latissimus dorsi, and is inserted along with it into the ridge at the inner side of the groove that lodges the long head of the biceps. These two tendons are included in a common capsula, besides which the tendon of this muscle adheres to the os humen, by two other capsulæ which we find placed one above the other.

This muscle assists in the rotatory motion of the arm, and Lkewise in drawing it downwards and backwards; so that we may consider it as the congener of the latissimus dorsi.

TERES MINOR. Marginisus scapulotrochiterien of Dumas. This muscle seems to 306

The teres minor is a thin fleshy muscle, situated along the inferior edge of the infra spinatus, and is in part covered by the

posterior part of the deltoides

It arises fleshy from all the convex edge. of the inferior costa of the scapula; from thence it ascends obliquely upwards and forwards, and terminates in a flat tendon, which adheres to the lower and posterior part of the capsular ligament of the joint, and is inserted into the lower part of the great tuberosity of the os humeri, a little below the termination of the infra-spinatus.

The tendinous membrane, which is continued from the infra-spinatus, and spread over the teres minor, likewise forms a thin septum between the two muscles. In some subjects, however, they are so closely united, as to be with difficulty separated from each other. Some of the fibres of the teres minor are intermixed with those of the teres major and subscapularis.

The uses of this muscle are similar to

those of the infra spinatus.

> TESTA PROBATRIX. (Quasi tosto, from torreo, to burn.) A cupel or test. A pot for separating baser metals from gold and

TESTADO. (From testa, a shell; because it is covered with a shell ) A tortoise, a snail. An ulcer, which, like a snail, creeps under the skin.

TESTES CEREBRI. See Tubercula qua

drigemina.

TESTICLE. Testes. Orchis. called dydimi, and by some perin. Two little oval bodies situated within the scrotum, and covered by a strong, white and dense coat, called tunica albuginea iestis. Each testicle is composed of small vessels, bent in a serpentine direction, arising from the spermatic artery, and convoluted into little heaps, separated from one another by cellular partitions. In each partition there is a duct receiving semen from the small vessels; and all the ducts constitute a net which is attached to the tunica albuginea. From this net-work twenty or more vessels arise, all of which are variously contorted, and, being reflected, ascend to the posterior margin of the testis, where they unite into one common duct, bent into serpentine windings, and forming a hard body called the epididymis. The spermatic arteries are branches of the aorta. The spermatic veins empty themselves into the vena cava and emulgent vein. nerves of the testicle are branches of the lumbar and great intercostal nerve. The use of the testicle is to secrete the semen.

Testicle, swelled See Orchitis. TESTICULUS. (Testiculus, dim. of testis.) A small testicle. Also the orchis plant, so named from the resemblance of its roots to a testicle.

TESTICULUS CANINUS. See Satarion.

TESTIS. (A witness, the testes being the witnesses of our manhood ) See Testicle.

TETANOMATA. (From TETAVOW, to smooth.) Tetanothra. Medicines which smooth the

skin, and remove wrinkles.

TETANUS. (From Ture, to stretch.) Spasm with rigidity. Convulsio indica. Holotonicos. Rigor nervosus. A genus of disease in the class neuroses and order spusmi of Cullen; characterised by a spasmodic rigidity of almost the whole The varieties of tetanus are, 1. body. Opisthotonos, where the body is thrown back by spasmodic contractions of the muscles. 2. Emprosdotonos, the body being bent forwards. 3. Trismus, the locked jaw. Tetanus is often symptomatic of syphilis and worms.

These affections arise more frequently in warm climates that in cold ones, and are

kinds of green, and five of bohea. The from the deliciousness of its fruit.) Cacao former class includes, 1. Imperial or bloom ten, having a large leaf, a faint smell, and being of a light green colour. 2. Hyson, which has small curled leaves, of a green shade inclining to blue. 3 Single tea, thus termed from the place where it is cultivited. The bolicus comprehend: 1. Son- heal.) Therapia. The art of healing dischong, which, on inf sion, imparts a yellowish green colour. 2. Camho, a fine tea, emitting a fragrant violet smell, and yielding a pale shade; it receives its name from the province where it is reared 3. Pekoe tea is known by the small white flowers that are mixed with it. 4. Congo has a larger leaf than the preceding variety, and yields a deeper tint to water; and 5. Common bohea, the leaves of which are of an uniform green colour. There are besides other kinds of tea, sold under the names of gunpowder tea, &c. which differ from the preceding, only in the minuteness of their leaves, and being dried with additional care.

Much has been said and written on the medicinal properties of tea; in its natural state it is a narcotic plant, on which account the Chinese refrain from its use till it has been divested of this property by keeping it at least for twelve months. If, however, good tea be drunk in moderate quantities, with sufficient milk and sugar, it invigorates the system, and produces a temporary exhibaration; but when taken too copionsly, it is apt to occasion weakness, tremor, palsies, and various other symptoms arising from narcotic plants, while it contributes to aggravate hysterical and hypochondriacal complaints. Tea has also been supposed to possess considerable diuretic and sudorific virtues, which, however, depend more on the quantity of warm water employed as a vehicle, than the quality of the tea itself. Lastly, as infusions of these leaves are the salest refreshment after undergoing great bodily fatigue or mental exertion; they afford an agrecable beverage to those who are exposed to cold weather; at the same time tending to support and promote perspiration, which is otherwise liable to be impeded.

THERAPEUTICS. (Therapeutica, from gaπευω, to cure.) Therapia. Metho-Bεξαπευω, to cure.) Therapia. Metho-dis medendi. That branch of medicine which treats of the operation of the different means employed for obviating diseases, and of the application of these

Theriaca. (From Sng, a viper or venomous wild beast.) Treacle, or molasses: also a medicine appropriated to the cure of the bites of venomous animals, or to resist poisons.

THERIACA ANDROMACHI. The Venice or Mithridate treacle; a composition of sixty-one ingredients, prepared, pulver-ised, and with honey formed into an electuary.

THERIACA CELESTIS. Liquid lauda.

THERIACA COMMUNIS. Common treacle, or molasses.

THERIACA DAMOCRATIS. An old preparation usually called Confectio Damo-

Edinburgh the. THERIACA EDINENSIS. riaca The thebaic electuary.

THERTACA JERMANORUM. A rob of juni-

per-berries.

THERIACA LONDINENSIS. A cataplasm of cummin seed, bay-berries, germander, snake-root, cloves and honey.

THERIACA RUSTICORUM. The roots of the common garlie were so called. See

Allium.

THERIOMA. (From Ongico, to rage like a wild beast ) A malignant ulcer.
THERME. Warm baths or springs. See

Medicinal waters.

THERMOMETER. (Thermometrum, from begun, heat, and mergew, to measure.) An instrument for measuring the degrees of heat. See Caloric.

Thigh bone. See Femer.

THIRST. Sitis. The sensation by which we experience a desire to drink. The seat of this sensation appears to be either in the fauces or the stomach

Thistle, carline. See Chameleon album.

Thiste, toly. See Cardina benedictus.
Thistle, pine. See Cardina gummifera.
THLASPI. (From 6120, to break, because its seed appears as if it were broken or bruised.) 1. The name of a genus

5 L

of plants in the Linnzan system. Class, Tetradynamia Order, Siliculosa.

2. The pharmaceutical name of the herb penny-cress. Two species of thlaspi are directed in some pharmacopias for medici. See Arbor vita. nal uses; -the Thlaspi arvense of Linnaus, or treacle mustard, and Thlaspi campestre of Linnxus, or mithridate mustard. seeds of both have an acrid biting taste approaching to that of common mustard, with which they agree nearly in their pharmaceutic qualities. They have also an unpleasant flavour, somewhat of the garlic or onion kind.

THLASPI ARVENSE. The systematic name of the treacte mustard. See Thlaspi.

The systematic THLASPI CAMPESTRE. name of the mithridate mustard. See Thlastn

THORACIC DUCT. Ductus thorathe absorbents; of a serpentine form, and about the diameter of a crow-quill. It resembles that of our mezereum. Garou lies upon the dorsal vertebræ, between the bark is to be immersed in vinegar for aorta and vena azygos, and extends from about an hour before it is wanted, a small the posterior opening of the diaphragm piece, the size of a sixpence, thus steeped, to the angle formed by the union of the is applied to the arm or any other part, subclavian and jugular veins, into which and renewed once a day in winter and it opens and evacuates its contents. In twice in summer. It produces a serous this course the thoracic duct receives the exudation from the skin without irritating absorbent vessels from every part of the or blistering. It is recommended, and is body.

THORAX. (From Dapea, to leap, be- against some diseases of the eyes. cause in it the heart leaps.) The chest. That part of the body situated between the neck and the abdomen. The external wood. Thus judeorum. A bark in small parts of the thorax are, the common integuments, the breasts, various muscles, and of leaves, seeming as if the bark and leaves the bones of the thorax. (See Bones and had been bruised and pressed together, Respiration.) The parts within the cavity brought from Syria, Cicilia, &c. and supof the thorax are, the pleura and its pro- posed to be the produce of the liquid ductions, the lungs, heart, thymus gland, storax tree. This bark has an agreeable ductions, the lungs, heart, thymus gland, osophagus, thoracic duct, arch of the balsamic smell, approaching to that of aorta, part of the vena cava, vena azygos, liquid storax, and a sub-acrid bitterish the eighth pair of nerves, and part of the taste accompanied with some slight adgreat intercostal nerve.

Thorn, Egyptian. The Mimosa nilotica

See Arabic gum. of Linnæus

Thorn-apple See Stramonium. Thorn, black. See Prunus sylvestris.

THROMBUS. (From Seew, to disturb.) A small tumour which sometimes arises after bleeding, from the blood escaping from the vein into the cellular structure surrounding it.

Thrush. See Aphtha.

(From beunta, to break.) THRYPTICA. Lithontriptics, medicines which are said to have the power of destroying stones in the bladder.

The cascarilla and THURIS CORTEX. eleuthera barks, were so called. See

THUS. (From Dvw, to sacrifice, so called from its great use in sacrifices.) Olibanum

THUS JUDEORUM. See Thymiama.

THUS MASCULUM. See Olibanum.

THUYA OCCIDENTALIS. (Thuya, from 600); odour, so named from its fragrant smell.) The systematic name of the tree of life,

THYLACITIS. (From bunaxos, a seed. vessel, so called from its large head.) The white garden poppy.

(From bunes, thyme; so THYMBRA. named because it smells like thyme.) See Satureja.

THYMBRA HISPANICA. The name given by Tournefourt to the common herb mas. tich. Se e Marum vulgare.

Thyme, lemon. See Serpyllum citratum. Thyme, mother of. Sce Serpyllum.

THYMELEA. (From buna, an odour, because of its smell.) Oneoron. Spurgeflax. Flax-leaved Daphne. This plant, Daphne guidium : panicula terminali foliis Ductus Pecquettii. The trunk of lineari-lauceolatis accuminatis of Linnaus, affords the garou bark, which very much in frequent use in France and Russia

THYMIAMA (From buma, an odour, so called from its odoriferous smell) Muskbrownish grey pieces, intermixed with bits

stringency.

THYMIUM. (From bumos, thyme, because it is of the colour of thyme.) A small wart upon the skin.

(From Bupos, thyme, THYMOXALME. ogus, acid, and axs, salt.) A composition of

thyme, vinegar and salt.

THYMUS. (A TO TE Suma, because it was used in faintings; or from Jupa, an odour, because of its fragrant smell.) 1. A gland of considerable size in the fætus, situated in the anterior duplicature or space of the mediastinum, under the superior part of the sternum. An excretory duct has not yet been detected, but lymphatic vessels have been seen going from it to the thoracic duct. Its use is unknown,

2. A small indolent carnous tubercle like a wart arising about the anus, or the pudenda, resembling the flowers of thyme, from whence it takes its name.

Class, Didynamia. Or- and its use is not yet known. Linnæan system

der, Gymnospermia. Thym ..

unigaris of Linnaus; -erectus foliis revo- Fosilus; and, from its resemblance to an butis ovatis, floribus verticillato spicatis, old musical instrument, Canna major; has an agrecable aromatic smell, and a Canna-domestica cruris. The largest bone warm pungent taste. Its virtues are said of the leg. It is of a long, thick and trito be resolvent, emmenagogue, tonic, and angular shape, and is situated on the instomachic; yet there is no disease men- ternal part of the leg. Its upper extremity tioned in which its use is particularly re- is large, and flattened at its summit, where commended by any writer on the materia we observe two articulating surfaces, a little medica.

THYMUS CRETICUS. bears this name in some pharmacopæias external one is rounded, and more superis the Satureja capitata of Linnaus, which ficial. Each of these, in the recent sub-possesses similar virtues to our thyme, but ject, is covered by a cartilage, which in a strenger degree.

3. The name of a genus of plants in the excretory duct has never been detected,

TIBIA. (Tibia, the hautboy, qu. tubia, 4. The pharmacopæial name of the from tuba, a tube; so called from its pipe-common thyme. This herb, the Thymus like shape.) Focile majus; Arundo major; concave, and separated from each other THYMUS CITHATUS. See Serpyllum citra. by an intermediate irregular protuberance. Of these two cavities, the internal one is The plant which deepest, and of an oblong shape, while the extends to the intermediate protuberance, The systematic where it terminates. These two little name of the common herb mastich. See cavities receive the condyles of the os femoris, and the eminence between them The systematic is admitted into the cavity which is seen name of the mother of thyme. See Serpyl. between the two condyles of that bone; so that this articulation affords a specimen of The systematic the complete ginglimus. Behind the ina pretty deep depression, which serves for Names compounded with the attachment of a ligament, and likethis word belong to muscles which are at. wise to separate the two cavities from each other. Under the edge of the ex-(Muscu- ternal cavity is a circular flat surface, tenoid cartilage forwards nearer to the fore part of the bone is a considerable middle of the thyroid, and consequently tuberosity, of an nch and a half in length, shortens and relaxes the ligament of the to which the strong ligament of the rotula is fixed

The body of the tibia is smaller than hyordeus.) A muscle, situated between its extremities, and, being of a triangular shape, affords three surfices. Of these, the external one is broad, and slightly hollowed by muscles above and below; Constrictor the internal surface is broad and flat, and the poster or surface is narrower than the Thyno-pharyngo starmilinus. See Pa- other two, and nearly cylindrical. This last has a slight ridge running obliquely across it, from the outer side of the upper end of the bone to about one-third of its THYROID CARTILAGE. (Cartilago length downwards. A little below this thyroidea, from Dugeoc, a shield, and aboc, we observe a passage for the medullary. resemblance, from its supposed resem vessels, which is pretty considerable, and blance to a shield.) Scutiform cartilage, slants obliquely downwards. Of the three The cartilage which is placed perpendicu- angles which separate these surfaces, the lar to the cricoid cartilages of the laryux, anterior one, from its sharpness, is called constituting the anterior, superior, and the spine, or shin. This rudge is not straight, largest part of the larynx. It is harder but describes a figure like an Italic f, and more prominent in men than in wo- turning first inwards, then outwards, and men, in whom it forms the pomum adami. Lastly inwards again. The external angle Glandala thyrois is more rounded, and serves for the at-

lower extremity, and terminates in a pretty deep cavity, by which it is articulated with the uppermost bone of the foot. This cavity, in the recent subject, is lined with cartilage. Its internal side is formed into a considerable process, called malleolus internus, which, in its situation, resembles the styloid process of the radius. This process is broad, and of considerable thickness, and from it ligaments are extended smell, in which their virtue seems to conto the foot. At its back part we find a sist, and abound with a strong mucilage. groove, lined with a thin layer of cartilage, in which slide the tendons of the flexor digitorum longus, and of the tibialis posticus; and a little behind this is a smaller groove, for the tendon of the flexor longus potlicis. On the side opposite to the malleolus internus, the cavity is interrupted, and immediately above it is a rough triangular depression, which is furnished with cartilage, and receives the lower end of the fibula,

The whole of this lower extremity of the bone seems to be turned somewhat outwards, so that the malleolus internus is situated more forwards than the inner border of the upper extremity of the

bone.

In the fætus both ends of the tibia are cartilaginous, and become afterwards epi-

physes.

TIBIAL ARTERIES. Arteriæ tibiales. The two principal branches of the popliteal artery: the o e proceeds forwards, and is called the auterior tibial; the other the native xid, termed so from its fibrous backwards, and is called the posterior ti- texture. This variety has hitherto been bial; of which the external tibial, the fiber found only in Cornwall. It occurs in fraglar, the external and internal plantar, and the plantal arch, are branches.

TIBIALIS ANTICUS. (Musculus tibialis anticus.) Tibio-sus-metatarsien of Dumas A flexor muscle of the foot, situated on the leg, which bends the foot by drawing it upwards and at the same time turns

the toes inwards

TIBIALIS GRACILIS. See Plantaris.

TIBIALIS POSTICUS (Musculus tibialis posticus ) Tibio tursien of Dumas. A flexor muscle of the foot, situated on the leg, which extends the foot, and turns the toes inwards.

A painful affec-TIC DOLOUREUX tion of the nerves of the face, particularly of that branch of the lifth pair, which comes out of the infraorbitary foramen.

Grana tilli. TIGETA GRANA. tiglii The grana tilia are seeds of a dark grey colour, the produce of Troton tylium of Linnaus, in shape very like the seed of the ricinus communis. They abound with an oil which is far more acrid and purgative than castor-oil.

TILBURY WATER. This is found at West Tilbury in Essex. It is an aperient and chalybeate now seldom used medici-

nally.

TILIA. (Please, ulmus, the elm-tree.) 1. The name of a genus of plants in the Linnæan sys'em. Class, Polyandria. Or-

der, Monogynia.

2. The pharmacopoial name of the lime or linden tree. Tilia Europea of Linnaus. The flowers of this tree are supposed to possess anodyne and antispasmodic virtues. They have a moderately strong They are in high esteem in France.

TILIA EUROPÆA. The systematic name

of the lime-tree. See Tilia.
TILIA GRANA. See Tiglio Grana.

TILMUS. (From TINAW, to pluck.) Floccitatio or picking of bed-clothes, observable in the last stages of some disorders.

TIMAC. The name of a root imported from the East Indies, which is said to possess diuretic virtues, and therefore exhibited in dropsies It is not known from

what plant it is obtained.

TIN. Stannum. Jupiter of the alchemis:s It has been much doubted whether this metal is found native. In the opinion of Kirwan there are sufficient authorities to determine the question in the affirmative. The native oxid of tin, or tin stone, occurs both massive and crystallized. Its colour is a dark brown, sometimes yellowish grey. When crystallized, it is somewhat transparent. The wood tin ore is a variety of ments which are generally round, and its colour is brown, sometimes inclining to yellow. Tin is also found mineralized by sulphur, associated always with a portion of copper, and often of iron. This ore is called tin pyrites Its colour is yellowish grey. It has a metallic lustre, and a fibrous or lamellated texture; sometimes it exhibits prismatic colours. Tin is comparatively a rare metal, as it is not found in great quantity any where but in Cornwall or Devonshire; though it is likewise met with in the mines of Bohemia, Saxony, the island of Buca, the peninsula of Malacca, and in the East Indies.

Properties of tin .- Tin is of a brilliant white colour, though not quite so white as silver. It is one of the lightest of the metals; its specific gravity, when ham-mered, being 7299. It is very fusible, melting at about 410° Fahr. By intense heat it is volatilized. It becomes oxidated by a moderate degree of heat. It easily bends and emits a noise, called the crackling of tin. It is exceedingly soft and ductile. It may be reduced to very thin leaves. Tin foil, or tin leaf, which is tin beat out, is about one-thousandth part of an inch thick. It has scarcely any sound.

tallizes in rhombs formed of small octable. matter of vegetables, and generally those dra. It unites, by fusion, with phosphorus parts of animal bodies in which their pecuand suphur. It does not decompose liar smell and taste reside. water alone, or in the cold; but easily by means of many other bodies. It decom- tracted almost equally by water and recposes the sulphuric acid, and unites with tified spirit; but in the watery and spiritthe sulphureous acid. It decomposes the wows tinctures of them there is this differ nitric acid, and is very soluble in murianc ence, that the active par s in the watery acid. Phosphoric acid at acks it by heat. Tartareous acid has measure depends, while rectified spirit no perceptible action on it. The oxalic extracts them almost pure from gum. and acetic a ids dissolve it in small quan- Hence, when the spirituous tinctures are tities. The alkalies appear to have some mixed with watery liquors, a part of what action on it by heat. I combines with the spirit had taken up from the subject sulphuret of polash by fusion. It unit s generally separates and subsides, on acwith the greater number of the met As with count of its having been freed from that facility. It decomposes muriate of mer- matter, which, being blended with it in cury and muriate of ammonia. I causes the original vegetable, made it soluble in nitrate of potash to de onate. It takes fire spontaneously in oxigenated muriatic acid gas, and is capable of combining with two different proportions of oxigen.

Method of obtaining tin-In order to in both mensiqua. obtain tin from its ore, a mere fusion of it, with pounded charcoal, is sufficient. Or, a certain quantity of the ore is first freed from sulphur and arsen c by torrifaction; after which it is mixed with equal parts of potash, one half of common resin, and two their green tincture, which for the most parts of black flux; the mixture is then fused in a crucible covered with charcoal, by means of which the inetal is recovered in its metallic state. In order to obtain of spirituous tinctures; and hence they pure tin, let the tin obtained before be rapidly dissolved in strong mitric acid with heat. Thus some of the metals it may this does not appear from experience; in contain will be held in solution, and others the trials which have been made no more become oxidated, but muriatic, or nitro- was found to be taken up in the deepmuriatic acid will, on digestion, take up coloured tinciures than in the paler ones, those oxids, and after sufficient ablution, and often not so much; if the alkali be leave that of tin, which may afterwards added after the extraction of the tincture, be reduced by mixing it when pulverised it will heighten the colour as much as when with double its weight of a flux formed of mixed with the ingredients at first equal parts of pitch and borax, or resin and addition of these salts in making tinctures borax, and puting it into a covered cruci- is not only needless but prejudicial, as they ble, lined with charcoal, which must be generally injure the flavour of aromatics, placed in a forge, and strongly heated for and superadd a quality sometimes contraa quarter of an hour.

TINCE OS. (Tinca, a tench.) The mouth of the uterus is so called by some writers, from its resemblance to a tench's mouth.

TINCAL. See Borax.

Tixcrories. (From tingo, to die.) An epithet of a species of broom used by dyers: the genista tinctoria of Lungus.

TINCTURA. (From tingo, to dye a tinctura.) A solution of any substance in spirit of wine. Recaified spirit of wine is tified spirit, four fluidounces." the direct menstraum of the resins, and in a sand bath until the extract is dissolved, essential oils of vegetables, and totally and then strain. This preparation posextracts these active principles from sun- sesses stomachic and purgative qualities, dry vegetable matters, which yield them but should never be given where there is a to water not at all, or only in part. It tendency to hamorrhoids. In choleric

It resists the action of the air. It crys- dissolves likewise the sweet saccharine

The virtues of many vegetables are extheir solubility in this menstrum in a great water. This, however, is not universal, for active parts of some vegetables when extracted by rectified spirits, are not precipitated by water, being almost soluble

Rectified spirit may be tinged by vegetables of all colours, except blue: the leaves of plants, in general, will give out little of their natural colour to watery liquors, communica e to spirit the whole of part proves elegant, though not very durable.

Fixed alkaline salts deepen the colour have been supposed to promote the dissolving power of the menstruum, though ry to the intention of the medicine.

Volatile alkaline salts, in many cases, promote the action of the spirits. generally weaken it; unless when the acid has been previously combined with the vinous spirit into a compound of new qualities, called dulcified spirit.

TINCTURA ALOES. Tincture of aloe. "Take of the inspissated juice of spike aloe, half an ounce; extract of liquorice, an ounce and half; water, a pint; rec- . Macerate

cases and amennorhea it is preferred to other purges. The dose is from half a fluidounce to an onnce.

TINCTURA ALOES COMPOSITA. Compound tincture of aloe, formerly called Elixir aloes: Elixir proprietatis. "Take of extract of spiked aloe, powdered, saffron, of each three ounces; uncture of myrrh, two pints." Macerate for fourteen days, and strain. A more stimulating compound than the former. It is a useful application to old indolent ulcers. The dose is from half a fluiddrachm to two drachms.

TINCTURA ALOES VITRIOLATA. With the bitter inf sion a drachm or two of this clegant tincture is extremely serviceable against gonly and rheumatic affections of the stomach and bowels, and also in the weaknesses of those organs which frequent-

ly attend old age.

TINCTURA ASSAFŒTIDÆ. Tinc ure of assafætida, formerly known by the name tinctura fætida. "Take of assafætida, four onnces; rectified spirit, two pints." Macerate for fourteen days and strain. Diluted with water, this is mostly given in all kinds of fits, by the vulgar. It is a useful preparation as an antispasmodic, especially in conjunction with vitriolated zinc. The dose is from half a fluiddrachm to two drachms.

TINCTURA AURANTII. Tincture of orangepeel, formerly tinctura corticis aurantii. "Take of fresh orange-peel, three ounces; proof spirit, two pints." Macerate for fourteen days, and strain. A mild and

pleasant stomachic bitter.

TINCTURA BENZOINI COMPOSITA. Compound tincture of benzoin, formerly known by the names of tinctura benzoes composita, and balsamum traumaticum. " Take of benzoin, three ounces; storax balsam, strained, two ounces; balsam of Tolu, an ounce; extract of spiked aloe, an ounce and half; rectified spirit, two pints."
Macerate for fourteen days, and strain This tincure is more generally applied externally to ulcers and wounds than given internally, though possessing ex- Tinotura cascarilla. Tincture of pectorant, antispasmodic, and stimulat- cascarilla. "Take of cascarilla-bark, ing powers. Against coughs, spasmodic powdered, four ounces; proof spirit, two ing powers. Against coughs, spasmodic affections of the stomach and bowels, and diarrhea, produced by illegrations of strain. A stimulating aromatic tonic, that those parts, it is a very excellent medianay be exhibited in debility of the bowels cine. The dose when given internally is from half a fluiddrachm to two drachms dil ted.

Tincture of ca-TINCTURA CALUMBR. lumba, formerly called tinctura columbæ. "Take of calumba root, powdered, two ounces and a half; proof spirit, two pints." Macerate for fourteen days, and strain. This tincture contains the active part of stimulant and antispasmodic, mostly exhithe root, and is generally given with the infusion of it, as a stomachic and adstringent.

TINCTURA CAMPHONE COMPOSITA. Compound tincture of camphor, fowerly called tinctura opii comphoratu; and chair "Take of camphor, two paregoricum. screples; opiom, dred and powdered. benzoic acid, of each a drachn; proof spirit, two pints." Macerate for fourteen days, and strain. The London college has changed the name of this preparation, because it was occasionally the source of mistakes under its old one, and tincture of opium was sometimes substituted for it. It differs also from the former preparation in the omission of the oil of aniseed, which was often complained of as disagreeable to the palate, and to which, as an addition, no increase of power could be affixed. The dose is from half a fluiddrachm to half an ounce.

TINCTURA CANTHARIDIS. See Tinctura Lytta.

TINCTURA CAPSICI. Tincture of capsi-"Take of capsicum berries, an onnce; proof spirit, two pints." Macerate for fourteen days, and strain.

Tincture of TINCTURA CARDAMOMI. "Take of cardamom-seeds, cardamom. bruised, three ounces; proof spirit, two pints." Macerate for fourteen days, and strain. A powerful stimulating carminative. In spasm of the stomach, an ounce with some other diluted stimulant is given with advantage. The dose may vary according to circumstances, from half a drachm to an ounce and upwards.

TINCTURA CARDAMOMI COMPOSITA pound tincture of cardamom, formerly called tinctura stomuchica. "Take of called tinctura stomachica. cardamom-seeds, carraway-seeds, cochineal, of each bruised, two drachms; cinnamon-bark, bruised, halfan ounce; raisins, stoned, four ounces; proof spirit, two pmis." Macerate for fourteen days, and strain. A useful and elegant carminative and cordial The dose from half a fluiddrachm to half an ounce and upwards.

pints." Macerate for fourteen days, and may be exhibited in debility of the bowels and stomach, and in those cases of fever in which the Peruvian bark proves purgative. The dosc from half a drachm to two drachms.

TINCTURA CASTOREI. Tincture of castor. " Take of castor, powdered, two ounces; rectified spirit, two pints." Macerate for fourteen days, and strain. A powerful bited in hysterical affections in a dilute form. The close is from half a fluiddrachm to two drachms.

TIN

chu, formerly known by the name tinctura in the cure of dropsical and other cachecjaponica. "Take of extract of catechu, tie diseases. The dose is from half a cumamon-bark, bruised, of each two oun-fluiddrachm to two drachms. ces; proof spirit, two pints." Macerate TINCTURA FERRI MURIATIS. for fourteen days, and strain. An aroma- of muriate of iron. Formerly called tinctic adstringent, mostly given to the hys- tura martis in spiritu salis: tinctura martis terical epilepsy of young women, which cum spiritu salis: and lately known by the arises from irregularity in the menstrual name of tinctura ferri muriati. "Take of discharge. The dose is from half a fluid- subcarbonate of iron half a pound; mu-

chona. Formerly known by the name of of iron in a glass vessel, and shake it octinctura corticis peruviani simplex. "Take ensonally for three days. Set it by, that of lance-leaved cinchona bark, powdered, the faces, if there be any, may subside; seven ounces; proof spirit, two pints." then pour off the solution, and add the Macerate for fourteen days, and strain. spirit. Mr. Cline strongly recommends The dose is from a draelim to half a fluidounce. For its virtues see Cinchona.

TINCTURA CINCHONA COMPOSITA. Compound tinetura of cinehona. "Take of chalybeate, and serviceable against most lanee-leaved cinchona bark, powdered, two ounces; orange-peel, dried, an ounce and half; serpentary root, bruised, three drachms; salfron, a drachm; eochineal, powdered, two scriples; proof spirit, twenty fluidonnees." Macerate for four-teen days, and strain. The dose is from one fluiddrachm to half an ounce. For its virtues see Cinchona.

TINCTURA CINNAMOMI. Tincture of cinnamon Formerly ealled aqua ciunamomi fortis. "Take of e mnamon bark, bruised, three ounces; proof spirit, two pints"
Macerate for fourteen days. The dose is from a fluiddraelim to three drachms or

TINCTURA CINNAMOMI COMPOSITA Compound lineture of cinnamon Formerly called tinctura aromatica. " Take of cinnamon bark, bruised, six drachms; eardamom-seeds, bruised, three draelims; long pepper, powdered, ginger-root, sliced. of each two drachms; proof spirit, two pints." Maeerate for fourteen days, and strain. The dose is from half a fluiddrachm to two drachms or more.

TINCTURA DIGITALIS Tincture of foxglove. "Take of fox-glove leaves, dried, four ounces; proof spirit, two pints." Matincture is introduced in the London Pharthe plant in a convenient, uniform, and permanent form; it is a saturated tineture, and in the same proportions h s been long used in general practice. The dose is from ten 10 forty minims. For its virtues see Digitalis.

tura ferri ammoniacalis: tinctura florum rationsofthis bitter have lately been strong-martialium, tinctura martis mynsichti. "Take ly recommended by Mr. Freke, (Obserspirit, a pint." Digest and strain. This ployed by many practitioners, who believe is a most excellent chalybeate in all atonic that it unites sedative and tonic powers,

TINCTURA CATECHU. Tincture of cate- affections, and may be given with cinchona

drachm to two drachms.

Tineture of ein-pints." Pour the acid upon the carbonate this in ischuria and many diseases of the kidneys and urinary passages. The dose is from ten to twenty drops. It is a good diseases of debility without fever.

TINCTURA GENTIANA COMPOSITA pound tineture of gentian. Formerly ealled tinctura amara, "Take of gentian root, sliced, two ounces; orange-peel, dried, an ounce; eardamom-seeds, bruised, half an ounce; proof spirit, two pints." Maccrate for fourteen days, and strain. The dose is from one fleiddrachm to two drachins For its virtues see Gentiana.

TINCTURA GUALACI. Tincture of guaia-cum. "Take of guaiacum gum resin, half a pound; reet fied spirit, two pints." Macerate for fourteen days, and strain. This tincture, which possesses all the active parts of this peculiar vegetable matter, is now first introduced into the London Pharmacopæia. The dose is from one fluiddrachm to two drachms. For its virtues see Guatacum.

TINCTURA GUAIACI AMMONIATA. Ammoniated tineture of guaiacum. Formerly ealled tinctura guaiacina volatilis "Take of gualacum gum resin, powdered, four ounces; compound spirit of ammonia, a pint and half." Macerate for fourteen days, and strain. The dose is from one fluiddrachm to two drachms.

TINCTURA HELLEBORI NIGRI. Tineture of cerate for fourteen days, and strain. This black hellebore Formerly called tinctura "Take of black helleboremelampodii macopeia as possessing the properties of root, sheed, four ounces; proof spirit, two pints." Maeerate for fourteen days, and strain. The dose is from half a fluiddrachm to a drachm. For its virtues consult Helleborns niger.

l'incrura numuli. Tineture of hop. "Take of hops, five ounces; proof spirit, TINCTURA FERRI AMMONIATI. Tineture two pints.' Macerate for fourteen days, and of ammoniated iron, formerly called tine. strain. TINEA CAPITIS. (Tinea, from teneo, to hold ) The sald-head A genus of disease in the class locales and order dialyses of Collen; characterised by small ulcers at the root of the hairs of the head, which produce a friable white erust.

Tiu-glass. See Bismuth.

TINNITUS AURIUM. See Paracusis.

TITANIUM. This is a lately disco-It was first noticed by vered metal Macgregor as existing in the state of an oxid, mixed with iron, manganese, and silex, in a greyish black sand found in the vale of Menachan in Cornwall, and thence named menachanite, or oxid of titanium, combined with iron. It has since been discovered by Klaproth, in an ore named titanite, or oxid of titanium, combined with lime and silex. This ore is generally met with crystallized in four-sided prisms, not longer than a quarter of an inch. Its colour is a yellowish red, or blackish brown; it is opaque and of an imperfect lustre. It breaks with a foliated, uneven, or conchoidal fracture. It exists also in an ore ealled red schorl of Hungary, or red oxid of titanium. This ore, which is found gcnerally erystallized in reetangular prisms. is of a brownish red colour; and its texture foliated. In all these ores titanium exists in the state of an oxid

Properties of titanium -Titanium has See Tinctura ja- been only obtained in very small agglatinated grains. It is of a red-yellow and crystalline texture, brittle and extremely refractory. Its specific gravity is about 4.2; when broken with a hammer while yet hot from its recent reduction it shows a change of colours of purple, violet, and blue. In very intense heat it is volatilized. Most of the acids have a striking ac-Tincture of senna. See Tinctura senna, tion on this metal. Nitrie and has little See Tinctura effect upon it. It is very oxidable by the muriatic acid. It is not attacked by the Tinctura alkalies. Nitro-muriatie acid converts it into a white powder. Sulphurie acid when boiled upon it is partly decomposed. It is one of the most infusible metals. It does Tincture of valerian, ammoniated. See not combine with sulphor, but it may be united to phosphorus. It does not alloy Tincture, compound, of aloes. tremely difficult to reduce the oxid of tita- the pia mater, give it a flocky appearance, nium to the metallic state. However, the TONIC SPASM. (Spasmus tonicus, experiments of Klaproth, Hecht and Vauquelin, have proved its reducibility. According to the two latter, one part of oxid of titanium is to be melted with six of potash; the mass when cold is to be dissolved in water. A white precipitate will be formed which is carbonate of titanium. This carbonate is then made into a paste with oil, and the mixture is put into a crucible filled with charcoal powder and The whole is then exa little alumine posed for a few hours to the action of a strong heat. The metallic titanium will be found in a blackish puffed-up substance, possessing a metallic appearance.

TOM

TITHEMALUS. (From TITHOS, a dug, and Maxos, tender; so called from its smooth leaves and milky juice.) Spurge. Two plants are directed for medicinal purposes by this name. See Tithymalus paralios

and Esula minor.

TITHYMALUS CYPARISSIUS. See Esula

TITHYMALUS PARALIOS. Sea spurge. Every part of this plant, Euthorbia jaralius of Linnæus, is violently camartic and irritating, inflaming the mouth and fauces. It is seldom employed in the practice of this country; but where it is used vinegar is recommended to correct its irritating power.

TITHYMELEA. See Thymelea.

(From titillo, to tickle; tory ducts. TITTILLICUM. so called from its being easily tickled.) The arm-pit.

Toad flax. See Linaria. Tobucco. See Nicotiana. Tobucco, English. See Nicotiana minor. Tobacco, Virginian. See Nicotiana.

TOES. Digiti pedis. They consist of dicines applied to a particular place. three distinct bones disposed in rows called phalanges, or ranks of the toes. The great toe has but two phalanges; the others have three ranks of bones, which have nothing particular, only the joints are made round and free, formed by a round head on one bone, and by a pretty deep hollow for receiving it, in the one above it.

TOPINARIA. A species of tumour in the skin of the head.

TORCULAR. (From torqueo, to twist) The tourniquet; a bandage to\_check hamorrhages after wounds or amputations.

FORCULAR HEROPHILI (Torcular, from torqueo, to twist.) Lechencon Lenos The press of Herophilus. That place where the four sinuses of the dura mater meet together, first accurately described by Herophilus, the anatomist.

TORDYLIUM OFFICINALE (Tordyllium quasi tortilium, from torqueo, to twist; so named from is tortuous branches) The systematic name of the officinal seseli creticum. See Seseli creticum.

Tormentil See Tormentilla.

TORMENTILLA. (From tormentum, pain in the teeth.) 1. The name of a genus of plants in the Linnæan system. Class, Icosandria. Order, Monogynia

2. The pharmacopoial name of the hep-

termentil, or upright septfoil. Tormentilla erecta of Linnaus:—caule erectiusculo, beam.) This word is mostly applied by foliis sessilibus. The root is the only part anatomists to the small medullary fibres of the plant which is used medicinally: of the brain, which constitute the commisit has a strong styptic taste, but imparts no sures. peculiar sapid flavour: it has been long held in estimation as a powerful adstrin- ness; from τεαχυς, rough.) The windgent; and, as a proof of its efficacy in this way, it has been substituted for oak-bark in the tanning of skins for leather. Tormentil is ordered in the pulvis crete compositus of the London Pharmacopæia.

TORMENTILLA ERECTA. The systematic name of the upright septfoil. See Tor-

mentilla.

TORMINA. Gripes. Pains in the bowels

TORPOR. A numbness, or deficient sensation.

TORTICOLLIS. (From torqueo, to twist, and collum, the neck.) The wry neck. TORTURA OSSIS. The locked jaw.

TOTA HONA. See Bonus Henricus.
TOUCH. Tactus. The sensation by which we perceive any thing that is applied to the skin. The organ of touch is formed by the nervous papilla, which are situated all over the skin, but more especially at the points of the fingers.

Touch me not. See Noli me tangere. Touch-wood See Agaricus.

TOURNIQUET. (French, from tour-ner, to turn.) An instrument used for stopping the flow of blood into a limb.

TOXICARIA MACASARIENSIS, An Indian poison, obtained from a tree hitherto undescribed by any medical botanist, known by the name of Boas-upas; it is a native of South America. Concerning this plant various and almost incredible particulars have been related, both in ancient and modern times; some of them true, others probably founded on superstition. Rumphius testifies that he had not met with any other more dreadful produced from any vegetable. And he adds, that this poison, of which the Indians boast, covered anteriorly by a considerable body, was much more terrible to the Dutch than any warlike instrument. He likewise says, it is his opinion, that it is of the same natural order if not of the same genus as the cestrum.

TUXICODENDRUM. (From Togicov, a poison, and ferdeor, a tree ) The poison-tree, which is so noxious that no insects ever

come near it.

TOXICOLOGY. (Toxicologia, from with some poisonous substance; and xoyos, a discourse.) A dissertation on poisons. Se Poison

TOXICUM. (From Togor, an arrow, which was sometimes poisoned.) Any deadly poison.

The artimesia or mug-TOXITESIA. wort.

TRABECULA. (Trabecula, a small

TRACHEA. (So called from its roughpipe. The trachea is a cartilaginous and membranous canal, through which the air passes into the lungs. Its upper part, which is called the larynx, is composed of five cartilages. The uppermost and smallest of these cartilages, is placed over the glottis or mouth of the larynx, and is called epiglottis, as closing the passage to the lungs in the act of swallowing. The sides of the larynx are composed of the two aryteno d cartilages, which are of a very complex figure, not easy to be described. The anterior and larger part of the larynx is made up of two cartilages, one of which is called thyroides or scutiformis, from its being shaped like a buckler; and the other cricoides or annularis, from its resembling a ring. Both these cartilages may be felt immediately under the skin, at the fore part of the thorax; and the thyroides, by its convexity, forms an eminence called the pomum adami, which is usually more considerable in the male than in the female subject.

All these cartilages are united to each other by means of very elastic ligamentous fibres; and are enabled by the assistance of their several muscles, to dilate or contract the passage of the larynx, and to perform that variety of motion which seems to point out the larynx, as the principal organ of the voice; for when the air passes out through a wound in the trachea, it produces

no sound.

These cartilages are moistened by a mucus, which seems to be secreted by minute glans situated near them. The upper part of the trachea, and the cricoid and thyroid cartilages, are in some measure which is supposed to be of a glandular structure, and from its situation is called the thyroid gland, though its excretory duct has not yet been discovered, or its real use astertained. The glottis is entirely covered by a very fine membrane, which is moistened by a constant supply of a watery fluid. From the larynx the canal begins to take the name of trachea or aspera arteria, and extends from thence as τοξον, an arrow or bow; because the darts far down as the fourth or fifth vertebræ of of the ancien's were usually besmeared the back, where it divides into two branches, which are the right and left brouchial tube. Each of these bronchia ramifies through the substance of that lobe of the lungs, to which it is distributed, by an infinite number of branches, which are formed of cartilages separated from each other like those of the trachea, by an intervening membranous and ligamentary

substance. Each of these cartilages is of transversalis cervicis and of the three supean angular figure; and as they become gradually less and less in their diameter, the lower ones are in some measure received into those above them, when the lungs, after being inflated, gradually collapse by the air being pushed out from them in expiration. As the branches of the bronchiæ cause of the rough cartilages.) The windbecome more minute, their cartilages become more and more angular and membranous, till at length they become perfeetly membranous, and at last become invisible. The trachea is furnished with fleshy or muscular fibres, some of which pass through its whole extent longitudinally, while the others are carried round it in a circular direction, so that by the contraction or relaxation of these fibres, it is enabled to shorten or lengthen itself, and likewise to dilate or contract the diameter of its passage. The trachea and its branches, in all their ramifications, are furnished with a great number of small glands which are lodged in their cellular substance, and discharge a mucous fluid on the inner surface of these tubes.

The cartilages of the trachea, by keeping it constantly open, afford a free passage to the air which we are obliged to be incessantly respiring; and its membranous part, by being capable of contraction or dilatation, enables us to receive and expel the air in a greater or less quantity, and with more or less velocity, as may be required in singing and declamation. membranous structure of the trachea posteriorly, seems likewise to assist in the descent of the food, by preventing that impediment to its passage down the osophagus, which might be expected, if the cartilages be complete rings. The trachea receives its arteries from the carotid and subclavian arteriés, and its veins pass into the jugulars. Its nerves arise from the recurrent branch of the eighth pair, and from the cervical plexus

TRACHELAGRA. (From τζαχηλος, the throat, and agea, a seizure.) The gout in the neck.

TRACHELIUM. (From reaxinos, the throat; so called from its efficacy in discases of the throat.) The herb throat wort.

(From Teaxnhos, the TRACHELO. neck ) Names compounded of bis word belong to muscles which are attached to the neck; as the

TRACHELOCELE. (From reaxera, the wind-pipe, and MANN, a tumour) A wen or tumour upon the trachea.

TRACHELO-MASTOIDEUS. A muscle situated on the neck, which assists the complexus, but pulls the head more to o e It is the complexus minor seu mustoideus lateralis of Winslow. Trachelo mas- ter a thick and glutinous consistence. The verse processes of the five inferior cervical considered as similar to those of gumarabic vertebra, where it is connected with the It is seldom given alone, but frequently in

rior dorsal, and it is inserted into the middle of the posterior part of the mastoid process.

TRACHELOPHYMA. (From τεαχηλος, the throat, and quaa, a tumour.) A swelling of the bronchial gland.

TRACHELOS. (From Teaxus, rough, be-

TRACHEOTOMY (Tracheotomia, from τραχυς, rough, and τεμνω, to cut.) Laryngotomia. A synonym of bronchotomy. See B onchotomy

TRACHOMA. (From reaxue, rough.) An asperity in the internal superfices of the eyelid. The effects are a violent ophthalmia, and a severe pain, as often as the evelid moves. The species are,

1. Trocoma subulosum, from sand falling between the eye and the eyelid of persons travelling, blown by a high wind; this happens chiefly in sabulous situations, and may be prevented by spectacles for the purpose, or by guarding against the flights of sand by covering the eyes.

2 Trachoma carunculosum, which arises from caruncles, or fleshy veruca, growing in the internal superfices of the evelid. This species of the trachoma is called morum palpebræ internæ, because the tuberculous internal superfices appears of a livid red like a mulberry Others call these carunculæ pladorotes.

3. Truchoma herpeticum, which are hard pustules in the internal superfices of the eyelids. This is also called fycosis, and palpebra ficosa, from its resemblance to granulated substances in a cut fig. the Greeks it is nominated atomable pharon, or proptoris.

Tragacanth gum. See Tragacantha. TRAGACANTHA. (From Teaper, 2 goat, and anav Da, a thorn; so called from its pods resembling the goat's beard.) Goat's thorn. Milk-vetch. Spina hirci. Astragulus aculeatus. We are indebted to a French traveller of the name of Olivier for the discovery that the gum tragacanth of commerce, is the produce of a species of astragulus not before known. describes it under the name of astragulus verus, being different both from A. tragacantha of Linnxus, and from the A. gummifera of Labillardiere. It grows in the North of Persia. Gum tragacanth, or gum dragant, (which is forced from this plant by the intensity of the solar rays, is concreted into irregular lumps or vermicular pieces, bent into a variety of shapes, and larger or smaller proportions, according to the size of the wound from which it issues,) differs from all other known gums in imparting to a very large quantity of wacombination with more powerful medicines, especially in the form of troches, for which it is peculiarly well adapted: it gives name to an officinal powder, and is an ingredient in the compound powder of cerus

TRAGICUS. (Musculus tragicus.) A proper muscle of the ear, which pulls the point of the tragus a little forward.

TRAGIUM. (From reapor, a goat; so named from its fil by smell.) Bastard dit-

tany.

Transcenus. (From rgayor, a goar, and regar, a horn; so named from the supposed resemblance of its leaves to the horn of a

goat ) The aloe

TRAGOPOGON. (From πραγος, a goat, and πωγων, a beard; so called be ause its downy seed, while enclosed in the calyx, resembles a go is beard) 1. The name of a genus of plants in the Lunnæan system. Class, Syngenesia. Order, Polygania.

2. The pharmacopeial name of the common goat's beard. The young stems of this plant, Tragopogon pratense of Linnus, are eaten like asparagus, and are a pleasant and wholesome food. The root is also excellent, and was formerly used medicinally as a diuretic.

THAGOPOGON PRATENSE. The systematic name of the common goat's beard. See

Tragopogon.

Thacopyrum. (From Tpayor, a goat, and Tugor, wheat; so named from its beard.) Buck-wheat.

Traconcurs (From reaver, a goat, and egge, a testicle; so named from the supposed resemblance of its roots to the testicles of a goat.) A species of orchis

The General Transfer of the Tr

marjoram

The soselinum. (From τg 2700, a goat, and σελινον, pursley; named from its harry coat like the beard of a goat.) The birner saxifrage was so called. See Pimpinella.

TRAGUS. (Tgayot, a goat; so called from its having numerous little hairs, or from its being hairy like the goat) A small cartilaginous eminence of the auricula or external ear, placed anteriorly, and connected to the anterior extremity of the helix. It is beset with numerous little hairs, defending in some measure the entrance of the external auditory passage.

Thans. (Tgamis) Raphe. The line which divides the scrotum, and runs on to

the anus

TRANSFUSION. (Transfusio, from transfundo, to pour from one vessel into another.) The transmission of blood from one animal to another by means of a cample.

TRANSPIRATION. (Transpiratio, from trans, through, and spire, to breathe.) A

synonym of perspiration. See Perspiration.

TRANSUDATION. The same as perspir tion

TRANSVERSALIS ABDOMINIS. A musch situated on the anterior part of the abdomien. It arises internally or posteriorly from the cartilages of the seven lower ribs, being there connected with the intercostals and diaphragm, also from the transverse process of the last vertebra of the back from these of the four upper vertebra of the loins, from the inner edge of the crista ilu and from part of Poupart's ligament, and it is inserted into the inferior bone of the sternum, and almost all the length of the linea aba. Its use is to support and compress the abdominal viscera.

TRANSVERSALIS ANTICUS PRIMUS. Sec Rectus capitis lateralis.

THANSVERSALIS CERVICIS. See Longissimus dorsi.

TRANSVERSALIS COLLI. A muscle, situated on the posterior part of the neck, which turns the neck obliquely backwards, and a little to one side.

Transversalis dorsi. See Multifidus spinæ.

TRANSVERSALIS MAJOR COLLI. See Longissimus dorsi.

Thansversalis pedis (Musculus transversalis pedis) A muscle of the foot, which it contracts by bringing the great toe and the two outermost toes nearer each other.

TRANSVERSE SUTURE. Sutura transversalis. This suture runs across the face, and sinks down into the orbits, joins the bones of the sak ill to the bones of the face; but with so many irregularities and interruptions, that it can scarcely be recognised as a suture.

Transverso-spinales, See Multifidus spinæ.

TRANSVERSIS AUMS. (Musculus transversus aurs.) A muscle of the external ear, which draws the upper part of the couch towards the helix.

TRANSVERSUS PERINÆI. (Musculus transversus perinæi) A muscle of the organs of generation, which sustains and keeps the perinæum in its proper place.

Thansvensus Peringi Alten. Infrrior prestate of Winslow. A small muscle occasionally found accompanying the former.

TRAPA NATANS. The systematic name of the plant which affords the nux aquatica. See Tribulus aquaticus.

TRAPEZIUM. (A four-sided figure; so called from its shape.) The first bone of the second row of the carpus.

TRAPEZIUS (Musculus trapezius, from τρατεξιος, four-square; so named from its shape) Cucullaris. A muscle situated immediately under the integuments of the

posterior part of the neck and back. It arises, by a thick, round, and short tendon, from the lower part of a protuberance in the middle of the occipital bone backwards, and from the rough line that is extended from thence towards the mastoid process of the os temporis, and by a thin membranous tendon, which covers part of the complexus and splenius. It then runs downwards along the nape of the neck, and rises tendious from the spinous processes of the two lowermost vertebræ of the neck, and from the spinous processes of all the vertebræ of the back, being inseparably united to its fellow, the whole length of its origin, by tendinous fibres, which, in the nape of the neck, form what is called ligamentum colli, or the cervical ligament. It is inserted fleshy into the broad and posterior half of the clavicle, tendinous and fleshy into one half of the acromion, and into almost all the spine of the scapula.

This muscle serves to move the scapula in different directions. Its upper descending fibres pull it obliquely upwards; its middle transverse ones pull it directly backwards; its inferior fibres, which ascend obliquely upwards, draw it obliquely

downwards and backwards.

The upper part of the muscle acts upon the neck and head, the latter of which it draws backwards, and turns upon its axis. It likewise concurs with other muscles in counteracting the flexion of the head forwards.

TRAPEZOIDES OS. The second bone of the second row of the carpus; so called from its resemblance to the trapezium or quadrilateral geometrical figure.

TRAUMATIC. (From TPAUMA, a wound.)

Any thing relating to a wound. Travellers, joy See Vitalba.

Treacle. See Theriaca.

Treacle, mustard. See Thlaspi. Trefoil, marsh. See Trifolium paludo-

TREMOR. An involuntary trembling

of parts

TREPAN. Trephine. An instrument used by surgeons to remove a portion of bone from the skull

TREPHINE See Trepan.

Triangularis See Steruocostalis and De-

pressor anguli oris.

(From Teisa, to TRIBULUS AQUATICUS vex, an instrument of war to be thrown in the way to annoy the enemy's horse: hence the name of an herb from its resemblance to this instrument.) Nux aquatica. The fruit of the trapa nata of Linnæus, of a quadrangular and somewhat oval shape, including a nut of a sweet farinaceous flavour, somewhat like that of the chesnut, which is apt to constipate the bowels, and Produce disease; a poultice of these nuts sembles fine hair.) Common maiden-hair,

is said to be efficacious in resolving hard and indolent tumours.

TRICAUDALIS. (From tres, three, and cauda, a tail.) A muscle with three

TRICEPS ADDUCTOR FEMORIS. (Triceps, from tres, three, and caput, a head; having three heads) Under this appellation are comprehended three distinet muscles. See Adductor brevis, longus,

and magnus femoris.

See Retrahentes auris. TRICEPS AURIS. TRICEPS EXTENSOR CUBITI. This muscle, which occupies all the posterior part of the os humeri, is described as two distinct muscles by Douglas, and as three by Winslow. The upper part of its long head is covered by the deltoides: the rest of the muscle is situated immediately under the integuments.

It arises, as its name indicates, by three heads. The first, or long head, (the long head of the biceps externus, of Douglas; anconeus major, of Winslow, as it is called,) springs by a flat tendon of an lach in breadth, from the anterior extremity of the inferior costa of the scapula, near its neck, and below the origin of the teres minor. The second head, (the short head of the biceps externus of Douglas; anconeus externus of Winslow), arises by an acute tendinous and fleshy beginning, from the upper and outer part of the os humeri, at the bottom of its great tuberosity. third head, (brachialis externus of Douglas; anconeus internus of Winslow), which is the shortest of the three, originates by an acute fleshy beginning, from the back part of the os humeri, behind the flat tendon of the latissimus dorsi. These three portions unite about the middle of the arm, so as to form one thick and powerful muscle, which adheres to the os humeri to within an inch of the elbow, where it begins to form a broad tendon, which after adhering to the capsular ligament of the elbow, is inserted into the upper and outer part of the olecranon, and sends off a great number of fibres, which help to form the fascia on the outer part of the fore-arm. The use of this muscle is to extend the fore-arm.

TRICHIASIS. (From TRIE, a hair.) Trichia. Trichosis. Entropeon. chiasis. Districhiasis Capillitium. Distichia. A disease of the eye-lashes, in which they are turned in towards the bulb of the eye.

TRICHISMUS. (From bpig, hair.) A species of fracture which appears like a hair,

and is almost imperceptible.

TRICHOMA. (From rpixes, the hair.) The plaited hair. See Plica polonica.

TRICHOMANES. (From TPIXES, hair, and mayor, thin, lax; so called because it reor spleen-wort. Linnaus: - froudibus pinnatis, piunis subro- lachrymal, and nasal nerves; the superior tundis crenaus. This plant is admitted maxillary into the spheno-palatine, posteinto the Edinburgh Pharmacopæia: the rioralveolar, and infra-orbital nerves; and leaves have a mucilaginous, sweetish, subadstringent taste, without any particular flavour: they are esteemed useful in disorders of the breast, being supposed to promote the expectoration of tough phlegm, tematic name of the fanugrek. and to open obstructions of the viscera.

Turcuosis. See Plica polonica.

TRICHURIS. (From Tpig, a hair.) The

long hair-worm. See Worms. TRICUSPID VALVES. (Valvulæ tricuspides, from tres, three, and cuspis, a point; so called from their being threequinted) The name of the three valves situated at the origin of the aorta and pul-

monary artery.

See Trifolium paludosum. Trifoil, water. TRIFOLIUM. (From tres, three, and folium, a lcaf; so called because it has three leaves on each stalk.) The name of a genus of plants in the Linnzan system. Class, Pentandria. Order, Monogynia. Trefoil.

THIFOLIUM ACETOSUM. The wood-sorrel

was so called. See Lujula.

TRIFOLIUM AQUATICUM. See Trifolium paludosum.

THIFOLIUM ARVENSE. Harc's-foot trefoil or lagopodium.

TRIFOLIUM AUREUM. Herb trinity; noble liver-wort.

Melilotus. TRIFOLIUM CABALLINUM.

TRIFOLIUM CARULEUM. Sweet trefoil. TRIFOLIUM FALCATUM. The Auricula

muris. See Pilocella. TRIFOLIUM FIBRINUM. See Trifolium

paludosum.

TRIFOLIUM HEPATICUM. See Hepatica TRIFOLIUM MILILOTUS OFFICINALIS. The

systematic name of the officinal melilot. Sce Melilotus.

TRIFOLIUM ODORATUM. See Melilotus.
TRIFOLIUM PALI DOSUM. Trifolium aquaticum. Trifolium fibrinum. Menyanthes. Water-trefoil, or buck-bean Menganthes Water-trefoil, or buck-bean trifoliata of Linnaus :- foliis ternatis. The whole plant is so extremely bitter, that in some countries it is used as a substitute for hops, in the preparation of malt liquor. It is sometimes employed in country places as an active eccoprotic bitter in hydropic and rheumatic affections. Cases are related of its good effects in some cutancous diseases of the herpetic and seemingly cancerous kind.

TRIGEMINI. (Trigeminus, from tres, three, and geminus, double; three times double.) The fifth pair of nerves, which arise from the crura of the cerebellum, and are divided within the cavity of the cranium into three branches viz. the orbital, superior, and inferior maxillary. The Femur.

Asplenium trichomanes of orbital branch is divided into the frontal, the inferior maxillary into two branches, the internal lingual, and one more properly called the inferior maxillary.

> TRIGONELLA FENUM GRECUM. See

Fænum græcum.

TRINITATIS HERBA. See Hepatica nobilis.

Trinity-herb. See Hepatica nobilis.
Tripastrum archimedris. A surgical instrument for extending fractured limbs; so named because it resembled a machine invented by Apellides or Archimedes, for launching of ships, and because it was worked with three cords.

TRIQUETRA OSSICULA. (Triquetrus, from tres, three.) Ossicula Wormiana. The triangular-shaped bones, which are found mostly in the course of the lambdoidal

suture.

TRISMUS. (From τριζω, to gnash.) Locked jaw. Spastic rigidity of the under jaw Capistrum of Vogel. Dr. Cullen makes two species. 1. Trismus nascentium, attacking infants during the two first weeks from their birth. 2. Trismus traumaticus, attacking persons of all ages, and arising from cold or a wound. See Tetanus.

TRISSAGO. (Quasi tristago, from tristis, sad; because it dispels sadness.) The common germander is sometimes so called. See Chamedrys.

TRISSAGO PALUSTRIS. The water-germander was so called. See Scordium

TRITAOPHYA. (From Tpilatos, tertian, and qua, of a like nature, or original.) It is an epithet of a fever much of a nature with a tertian, and taking its rise from it. Some call it a continued tertian. It is remittent or intermittent.

TRITEOPHYA CAUSUS. The fever called

causus by Hippocrates.

TRITEUS Terraios. The same as Triteophya.

TRITICUM. (From tero, to thresh from the husk.) See Wheat.

TRITORIUM. (From trito, to beat small.) A mortar. Also a glass for separating the oil from the water in distilling.

TROCAR. (Corrupted from un trois quart, French, a three quarters, from the three sides with which the point is made.) The name of an instrument used in tapping

for the dropsy

TROCHANTER. (From TPEXa, to run; because the muscles inserted into them perform the office of running.) Two processes of the thigh bone, which are distinguished into the greater and lesser. See

TROCHISCI AMYLI. Starch lozenges are vertebra upon the odontoid process of the used in tickling coughs and acidities of second. the stomach and bowels.

TUBA EUSTACHIANA. Tuba Aristelica. Aquaducus. Aquaducus Fal-The auditory and partly membranous, narrow at the beginning, but becoming gradually larger, 1. If the mass prove so glutinous as to and ending in a pouch behind the soft pituitary membrane of the nose enters the tympanum. It is always open, and affords a free passage for the air into the tympanum; hence persons hear better with their mouth open.

FALLOPIANA. Tuba fallo-TUBA pina. The Fallopian tube first described by Fallopins. The uterine tabe. A canal included in two laminæ of the peritonæum, which arises at each side of the fundus of with its extremity turned downwards at the ovarium. Its use is to grasp the ovum, and convey the prolific vapour to it, and to conduct the fertilised ovum into the cavity

of the oterus.

A hard su-Tuber culum. TUBERCLE. perficial tumour, circomscribed and permanent: or proceeding very slowly to suppuration.

TUBERCULA QUADRIGEMINA. Corrotates upon another; as the first cervical gemina. Four white oval tubercles of the brain, two of which are situated on each lime, combined with the acid of this meside over the posterior orifice of the third tal. This ore is now called tungstate of twentriele and the aqueduct of Sylvius. The ancients called them nates and testes, from their supposed resemblance.

TUBERCULUM ANNULARE. The commencement of the medulla oblon-

gata.

TUBERGULUM LOWERI. An eminence in the right auricle of the heart where the two venæ cavæ meet; so called from Lower, who first described it.

TUBULI LACTIFERI. The duets or tubes in the nipple, through which the milk

passes.

TUMOR. A swelling.

TUMORES. (Tumor, from tumeo, to swell.) Tumours. An order in the class locales of Cullen's nosology, comprehending partial swellings without inflammation.

TUNBRIDGE WATER. Tunbridge Wells is a populous village in the county of Kent, which contains many chalybeare springs, all of which resemble each other very closely in their chemical properties. Two of these are chiefly used, which yield about a gallon in a minute, and therefore afford an abundant supply for the numerous invalids who yearly resort thither. The analysis of Tunbridge spring prove it to be a very pure water, as to the quantity of solid matter; and the saline contents (the iron excepted) are such as may be found in almost any water that is used as common drink. It is only as a chalybcate, and in the quantity of earhonic acid, that it differs from common water. Of this acid it contains one twenty second of its bulk. The general operation of this chalybeate water is to increase the power of the secretory system in a gradual, uniform manner, and to impart tone and strength to all the functions; hence it is asserted to be of eminent service in irregular digestion; flatulency; in the incipient stages of those chronic disorders, which are attended with great de-bility; in chloris; and numerous other complaints incident to the female sex. The prescribed method of using the Tunbridge water, observes Dr. Saunders, is judicious. The whole of the quantity daily used, is taken at about two or three intervals, bego ning at eight o'clock in the morning, and finishing about roon. The dose at each time varies from about one to three quarters of a pint; according to the age, sex, and general constitution of the patient, and especially the duration of the course, for it is found that these waters lose much of their effect by long habit.

TUNGSTEN (Tungsten, Swed ponderous stone.) This metal, which is never found but in combination, is by no means common. The substance known to mineralogists, under the name of tongsten, was, after some time, discovered to consist of

been found in Sweden and Germany, both in masses and crystallized, of a yellowish white, or grey colour. It has a sparry appearance, is shining, of a lamellated texture, and semi-transparent. The same metallic acid is likewise found united to iron and manganese; it then forms the ore called Wolfram, or tungstate of iron and manganese. This ore occurs both massive and crystallized, and is found in Cornwall, Germany, France and Spain. Its colour is brownish black, and its texture foliated. It has a metallic lustre, and a lamellated texture; it is brittle and very heavy; it is found in solid masses in the state of layers interspersed with quartz. These two substances are therefore ores of the same metal.

Properties .- Tungston appears of a steel grey colour. Its specific gravity is about 17.6. It is one of the hardest metals, but it is exceedingly brittle; and it is said to be almost as infusible as platina. Heated in the air it becomes converted into a yellow pulverulent oxid, which becomes blue by a strong heat or when exposed to light. Tungsten combines with phosphorus and sulphur, and with silver, copper, iron, lead, tin, antimony, and bismuth; but it does not unite with gold and platina. is not attacked by sulphuric, nitric, or muriatic acids; nitro muriatic acids acts upon it very slightly. It is oxidable and acidifiable by the nitrates and super-oxigenated muriates. It colours the vitrified carths or the vitreous fluxes, of a blue or brown colour. It is not known what its action will be on water and different oxids. Its action on the alkalies is likewise unknown. It is not employed yet, but promises real utility, on account of its colouring property, as a basis for pigment, since the compounds it is said to form with vegetable colouring matters, afford colours so permanent, as not to be acted on by the most concentrated oxigenated muriatic acid, the great enemy of vegetable colours.

Methods of obtaining Tungsten.—The method of obtaining metallic tungsten is a problem in chemistry. Scheele, Bergman, and Gmelin, did not succeed in their attempts to procure it. Klaproth tried to reduce the yellow oxid of this metal with a variety of combustible substances, but without success. Messrs Ruprecht and Tondy say they have obtained this metal by using combustible substances alone: and by a mixture of combustible and alkaling matter.

The following process is recommended by Richter, an ingenious German chemist.

\* 5 N

Let equal parts of tungstic acid and qualities which they possess in common and blood be exposed for some time to a They stimulate the prime vie, and prove dried blood be exposed for some time to a red heat in a crucible; press the black laxative; when carried into the blood. powder which is formed, into another smal- vessels they excite the whole system, and fer crucible, and expose it again to a vio- thus prove serviceable in chronic rheumalent heat in a forge, for at least half an tism and paralysis. maria delirium.) A complication of phrensy and lethargy with fever.

cause its leaves resemble those of the white species of continued fever, characterised The systematic name of the by great debility, a tendency in the fluids to putrefaction and the ordinary symptoms of fever. It is to be readily distinguished from the inflammatory by the smallness of the pulse and the sudden and great debility which ensues on its first attack; and, in its more advanced stage, by the petechiæ, or purple spots, which come out on various parts of the body, and the fetid stools which are discharged; and it may be distinguished from a nervous fever by the great violence of all its symptoms on its first coming on.

The most general course that gives rise to this disease, is contagion, applied either immediately from the body of a person labouring under it, or conveyed in clothes or merchandise, &c.; but it may be occasioned by the effluvia arising from either animal or vegetable substances in a decayed or putrid state; and hence it is, that in low and marshy countries it is apt to be prevalent when intense and sultry heat quickly succeeds any great inundation. of proper cleanliness and confined air are likewise causes of this fever; hence it prevails in hospitals, jails, camps, and on board of ships, especially when such places are much crowded, and the strictest attention is not paid to a free ventilation and due cleanliness. A close state of the atmosphere, with damp weather, is likewise apt to give rise to putrid fever. Those of lax fibres, and who have been weakened by any previous debilitating cause, such as poor diet, long fasting, hard labour, continucd want of sleep, &c. are most liable to

On the first coming on of the disease, the person is seized with languor, dejection of spirits, amazing depression and loss of muscular strength, universal weariness and soreness, pains in the head, back, and extremities and rigors; the eyes appear full, heavy, yellowish, and often a little inflamed; the temporal arteries throb vio bones of the ear. It begins behind the rupted with deep sighing; the breath is hot membrane of the tympanum, which termi- and offensive, the urme is crude and pale, lea of the labyrinth, and has opening into heat, load, and pain are felt at the pit of it four foramina, viz. the orifice of the Eus. the stomach, and a vomiting of bilious

UNCIFORM BONE. (Os unciforme, from uncus, a hook, and forma, a likeness.) The last bone of the second row of the earpus or wrist; so named from its hooklike process, which projects towards the palm of the hand, and gives origin to the great ligament by which the tendons of the wrist are wound down. See Carpal bones.

UNGUENTUM. (From ungo, to anoint.) An ointment. The usual consistence of thalmia, indolent tumours on the margin of ointments is about that of butter. The following are among the best formulæ.

Ung. Coutharidis. See Ceratum lytte. UNGUENTUM CETACEI. Ointment of spermaceti, formerly called linimentum album, and latterly unguentum spermaceti. " Take of spermaceti, six drachms; white wax, two drachms; olive oil, three fluidounces." Having melted them together over a slow fire, constantly stir the mixture until it gets cold. A simple emollient

oinment.

UNGUENTUM CICUTE. Hemlock oint-"Take of the fresh leaves of cicuta, and prepared hog's lard, of each four ounces." The cicuta is to be bruised in a marble mortar, after which the lard is to be added, and the two ingredients thoroughly incorporated by beating. They are then to be gently melted over the fire, and after being strained through a cloth, and the fibrous parts of the hemlock well pressed, the ointment is to be stirred till quite cold. To cancerous or scrophulous sores this ointment may be applied with a prospect of success.

UNGUENTUM ELEMI COMPOSITUM. Compound ointment of elemi, formerly called linimentum arcei and unguentum e gummi elemi. "Take of elemi, a pound; common turpentine, ten ounces; prepared suct, two pounds; olive oil, two fluidounces." Melt the clemi with the suet, then remove it from the fire, and immediately mix in the terpentine and oil, then strain the mixture through a linen cloth. Indolent ulcers, chilbiams, chronic ulcers after burns, and indolent tumours, are often

removed by this eintment.

UNGUENTUM HYDRARGYRI FORTIUS. Strong mercurial ointment, formerly called " Take of unguentum cæruleum fortuis. purified mercury, two pounds; prepared lard, twenty-three ounces: prepared suet, an ounce." First rub the mercury with the suet and a little of the lard, until the globules disappear; then add the remain- ment, formerly called unguentum picis;

etes about two inches all round the navel. use for mercurial frictions. It may be em-Cotyledon mari- ployed in almost all cases where mercury is indicated.

UNGUENTUM HYDRARGYRI MITIUS. Mild mercurial oiniment, formerly called unguentum caruleum mitius. " l'ake of strong mercurial ointment, a pound; prepared lard, two pounds." Mix. Weaker than the former.

UNGUENTUM HYDRARGIRI NITRATI. Ountment of nitrate of mercury, "Take of purified mercury, an ounce; nitric acid. two fluidounces; prepared lard, six ounces; olive oil, tour fluidounces." First dissolve the mercury in the acid, then, while the liquor is hot, mix it with the lard and oil melted together. A stimulating and detergent outment. Tinea capitis, prophthe eye-lid, and ulcers in the urethra, are cured by its application.

UNGUENTUM HYDRARGYRI NITRATI MITI-Weaker only than the former.

UNGUENTUM HYDRARGYRI NITRICO-OXYDI, Ointment of nitric oxyd of mercury. " Take of nitric oxyd of mercury, an ounce; white wax, two ounces; prepared lard, six ounces." Having melted together the wax and lard, add thereto the nitric oxyd of mercury in very fine powder, and mix. A most excellent stimulating and escharotic ointment.

UNGUENTUM HYDRARGYRI PR.ECIPITATE ALBI. Ointment of white præcipitate of mercury, formerly called unguentum e mercurio precipitato albo, and latterly unguentum calcis hydrargyri albi. " Take of white præcipitate of mercury, a drachm: prepared lard, an ounce and half." Having melted the lard over a slow fire, add the precipitated mercury, and mix. useful ointment to destroy vermin in the head, and to assist in the removal of scald head, venereal ulcers of children, and cutaneous eruptions.

UNGUENTUM See Ceratum LYTTÆ.

lytta.

UNGUENTUM OPHTHALMICUM. Ophthalmic ointment of Janin. "Take of prepared hogslard, half an ounce; prepared tutia, bole ammoniac, of each two drachms; white precipitate, one drachm." Mix. This celebrated ointment may be used for the same diseases of the eye and eyelid as the ung. hydrarg. nitrati. It must be at first weakened with about twice its quantity of hogslard.

UNGUENTUM PICIS ARIDÆ. Pitch ointment, formerly called unguentum basilicum nigrum vel tetrapharmacum. " Take of pitch, yellow wax, yellow resin, of each nine ounces; olive oil, a pint." Melt them together, and strain the mixture through a

linen cloth.

UNGUENTUM PICIS LIQUIDE.

unguentum e pice. "Take of tar, prepared found in one shell not any one of them suct, of each a pound." Men them loge- is like the other.) Pearls. See Margather, and strain the mixture through a linen cloth. The two preceding omtnients are applicable to cases of tinea capitis, and some eruptive complaints; also to some kinds of irritable sores.

UNGUENTUM RESINE FLAVE. Yellow basilicon is in general use as a stimulant and detersive: it is an elegant and useful form

of applying the resin

UNGUENTUM SAMBUCI. Elder ointment, formerly called unguentum sambucinum. "Take of elder flowers, two pounds; prepared lard, two pounds." Boil the elder flowers in the lard until they become crisp, then strain the ointment through a linen cloth. A cooling and entollient preparation

UNGUENTEM SULPHURIS. Sulphur ointment, formerly called unguentum e sulphore. " Take of sublimed sulphur, three ounces; prepared lard, half a pound." Mix. The most effectual preparation to destroy the itch. It is also serviceable in the cure of

other cutaneous eruptions.

UNGUENTUM SULPHURIS COMPOSITUM, Compound sulphur ointment. "Take of sublimed sulphur, half a pound; white hellebore root, powdered, two ounces; nitrate of potash, a drachm; soft soap, half a pound; prepared lard, a pound and half." Mix. This preparation is introduced into the last London pharmacopæia as a more efficacious remedy for iich than common sulphur ointment. In the army, where it is generally used, the sulphur vivum, or native admixture of sulphur with various lieterogeneous matters, is used instead of sublaned sulphur.

UNGUENTUM VEASTHI. White hellebore ointment, formerly called unguentum helle-bori albi. "Take of white hellebore root, powdered, two.ounces; prepared land, eight ounces; oil of lemons, twenty mi-

nims." Mix.

UNGUENTUM ZINCI. Zinc ointment. "Take of the oxyd of zinc, an ounce; prepared lard, six ounces." Mix. A very opaque, scoriaceous bead. It is soluble in useful application to chronic ophthalmia sulphuric, nitric, and muriatic acids. It and relaxed ulcers.

See Lachrymul bone.

UNGULA CABALLINA. See Tussilago.

UNIONES. (Umo, pl uniones, from unus, one; so called because there is never is thus completely dissolved, while part of more than one found in the same shell, or the sulphur remains undissolved, and part according to others, for that many being of it is dissipated under the form of sul-

rita.

URACHUS. (From spor, urine, and εχω, to contain.) Urinaculum The ligamentaus cord that arises from the basis of the urmary bladder, which it runs along, and terminares in the umbilical cord. In the fœtuses of brute animals, which the ancients mostly dissected, it is a hollow tube and conveys the urme to the allantoid membrane.

URAGIUM. (From searce, the hinder part of an army ) The apex or extreme

point of the heart.

URANISCUS. (From segros, the firmament; so called from its arch.) The palate.

URANIUM. This metal was discovered by Klaproth in the year 1789. It exists combined with sulphur, and a portion of iron, lead, and silex, in the mineral termed Pechblende, or oxid of uranium bined with carbonic acid it forms the chalcolite, or green mica: and mixt with oxid of mon, it constitutes the uranitic ochre. It is always found in the state of an oxid with a greater or smaller portion of iron, or mineralized with sulphur and copper. The ores of uranium are of a blackish colour, inclining to a dark iron grey, and of a moderate splendor; they are of a close texture, and when broken present a somewhat uneven, and in the smallest particles a conchoidal surface. They are found in the mines of Saxony.

Properties of Uranium.-Uranium exhibits a mass of small metallic globules, agglutinated together. Its colour is a deep grey on the outside, in the inside it is a pale brown. It is very porous, and is so soft that it may be scraped with a knife. It has but little lustre. Its specific gravity is 6.440. It is more difficult to be fused than even manganese. When intensely heated with phosphate of soda and aminonia, or glacial phosphoric acid, it fuses with them into a grass-green glass. With soda or borax it melts only into a grey, combines with sulphur and phosphorus, UNGUIS. (From over, a hook.) I The and alloys with mercury. It has not yet nail. The nails are horny lamme situated been combined with other combustible at the extremities of the fingers and toes, bodies. It decomposes the nitric acid and 2. An abscess or collection of pus be- becomes converted into a yellow oxid. The

Method of obtaining Uranium.- In order 3. The lachrynial bone is so named from to obtain uraniom, the pechblende is first its resemblance to a nail of the finger, freed from sulphur by heat, and cleared from the adhering impurities as carefully as possible. It is then digested in nitric acid; the metallic matter that it contains phurated hydrogen gas. The solution is by a longitudinal orifice, called meature then precipitated by a carbonated alkali. The precipitate has a lemon-yellow colour when it is pure. This yellow carbonate is made into a paste with oil and exposed to a violent heat, bedded in a crucible containing and lined with charcoal.

Klaproth obtained a metallic globule 28 grains in weight, by forming a ball of 50 grains of the yellow carbonate with a little wax, and by exposing this ball in a crucible lined with charcoal to a heat equal to

170° of Wedgwood's pyrometer.

Richter obtained in a single experiment 100 grains of this metal, which seemed to be free from all admixture.

URCEOLA. (From urceolus, a small pitcher; so named from its uses in scowering glazed vessels.) The herb fever few.

UREDO. (From uro, to burn.) An itching or burning sensation of the skin, which accompanies many diseases. The nettle-

rash is also so called.

URETER. (From 800, urine.) membranous canal which conveys the urine from the kidney to the urinary bladder; at its superior part it is considerably the largest, occupying the greatest portion of the pelvis of the kidney; it then contracts to the size of a goose-quill, and descends over the psoas magnus muscle and large crural vessels into the pelvis, in which it perforates the urinary bladder very obliquely. Its internal surface is lubricated with mucus to defend it from the irritation of the urine in passing.

URETERITIS. (From senting, the ure-

ter.) An inflammation of the ureter.

Unetericus. (From sentne, the ureter, or sentupitis, an inflamination of the ureter.) Applied to an ischury, or suppression of urine, from an inflammation of the ureter.

URETEROLITHICUS. (From senting, the ureter, and λιθον, a stone.) Applied to an

ischury from a stone in the ureter.

URETEROTHROMBOIDES. (From sentue, the ureter, and beoutes, grumous blood, and sidos, a likeness.) Applied to an ischury from grumous blood in the ureter.

URETEROPHLEGMATICUS. (From sgring, the ureter, and pasyma, phlegm.) Applied to a suppression of urine from pituitous

matter in the ureter.

Unetero-pricus. (From sgnrng, the ureter, and woor, pus.) Applied to an ischury from purulent matter in the ureter.

URETEROSTOMATICUS. (From senting, the ureter, and soma, a mouth ) Applied to a suppression of urine from an obstruction in the lower orifice of the ureter.

(From seer, the nrine; URETHRA because it is the canal through which the of an healthy men is divided in general into, urine passes ) A membranous canal running from the neck of the bladder through or two hours after eating; this is for the the inferior part of the penis to the extre- most part aqueous, and often vitiated by mity of the glans penis, in which it opens some foods, and,

urinarius. In this course it first passes through the prostate gland, which portion is distinguished by the name of the prostatical urethra; it then becomes much di-lated, and is known by the name of the bulbous part, in which is situated a cutaneous eminence called the caput gallinaginis or verumontanum, around which are ten or twelve orifices of the excretory ducts of the prostate gland, and two of the spermatic vessels. The remaining part of the urethra contains a number of triangular months, which are the lacune, or openings of the excretory ducts of the mucous glands of the urethra.

URETHELMINTHICUS. (From 20,002, the urethra, and ελμινθες, worms.) Applied to an ischury from worms in the urethra,

URETHRITICUS. (From senbeitic, an inflammation of the urethra.) Applied to a suppression of urine from an inflammation of the urethra.

URETHRITIS. (From sender, the urethra.) An inflammation in the urethra.

See Gonorrhea.

URETHROHYMENODES. (From sender, the urethra, and umnr, a membrane.) Applied to an ischury from a membrane obstructing the urethra.

URETHROLITHICUS. (From senbea, the urethra, and λιθος, a stone.) Applied to a suppression of urine from a stone in the

urethra.

URETHROMBOIDES. (From εgnθga, the urethra, and beomboidns, a grumous concretion.) A caruncle in the urethra,

URETHROPHLEGMATICUS. (From sender, the urethra, and φλεγμα, phlegm.) Applied to an ischury from mucus obstricting the urethra.

URETHRO-PTICUS. (From zenbea, the urethra, and avov, pus.) Applied to a suppression of urine from pus collected in the urethra.

URETICA. (From secv, urine.) Medicines which promote a discharge of urine.

URIAS. (From 890v, urine.) The urethra. URINE. (Urina; 8gov, from cesa, to rush out.) The saline liquid, secreted in the kidneys, and dropping down from them, guttatim, through the ureters, into the cavity of the urinary bladder. The secretory organ is composed of the arterious vessels of the cortical substance of the kidneys, from which the urine passes through the uriniferous tubuli and renal papillæ, into the renal pelvis: whence it flows drop by drop, through the ureters, into the cavity of the urinary bladder: where it is detained some hours, and at length, when abundant, eliminated through the urethra. The urine

1. Crude, or that which is emitted one

URINE: 833

2. Cocted, which is climinated some hours after the digestion of the food, as that which is emitted in the morning after steeping. This is generally in smaller quantity, thicker, more coloured, more acrid than at any other time. Of such cocted urine, the colour is usually citrine, and not unliandsome.

The degree of heat agrees with that of the blood; hence in atmospheric air it is warmer, as is perceived if the hand be washed with urine. The specific gra- evaporation of urine. vity is greater than water, and that emitted in the morning is always heavier than at any other time. The smell of fresh urine is not disagreeable. The taste is saltish and na seous. The consistence is somewhat thicker than water. The quantity depends on that of the liquid drink, its diviretic nature, and the temperature Scheele first ascertained to be crystals of of the air.

Changes of urine in the air. Preserved in an open vessel, it remains pellucid for some time, and at length there is perceived at the bottom a nubecula or little cloud, cially during diseases of the liver, a coconsolidated as it were from the gluten, pious sediment of a brick-red colour is de-This nubecula increases by degrees, occu- posited from urine. This sediment conpies all the urine, and renders it opaque. The natural smell is changed into a putrid cadaverous one; and the surface is now generally covered with a cuticle, composed of very minute crystals. At length the urine regains its transparency, and the colour is changed from a yellow to a brown; the cadaverous smell passes into an alkaline, and a brown grumous sediment falls to the bottom, filled with white particles, deliquescing in the air, and so congluti-nated as to form, as it were, little soft calculi.

Thus two sediments are distinguishable in the urine; the one white and gelatinous, and separated in the beginning; the other brown and grumous, deposited by the

urine when putrid.

Of all the Spontaneous degeneration. fluids of the body, the urine first putrefies. In summer, after a few hours it becomes turbid, and sordidly black; then deposits a copious sediment, and exhales a fetor, like that of putrid cancers, which, at length becomes cadaverous. Putrid urine effervesces with acids, and if distilled, gives off, before water, an urmous volatile spirit.

The proporties of healthy urinc, are,

1. Urine reddens paper stained with turnsole and with the juice of radishes, and therefore contains in acid. This acid has been generally considered as the phosphoric, but Thenard has shewn that in reality it is the acetic.

2. If a solution of ammonia be poured into fresh urine, a white powder precipitates, which has the properties of phosphate

of lime.

3. If the phosphate of lime precipitated from urine be examined, a little magnesia will be found mixed with it. Fourcroy and Vanquelin have ascertained that this is owing to a lit le phosphate of mugnesia which urine contains, and which is decomposed by the atkali of lime employed to precipitate the phosphate of lime.

4. Proust informs us that carbonic acid exists in urine, and that its separation occasions the froth which appears during the

5. Proust has observed, that nrine kept in new casks deposits small crystals, which effloresce in the air, and fall to powder. These crystals possess the properties of the carbonate of lime.

6. When fresh urine cools, it often lets fall a brick-coloured precipitate, which uric acid All urine contains this acid even when no sensible precipitate appears when it cools.

7. During intermitting fevers, and espetains the rosacic acid of Proust.

8. If fresh urine be evaporated to the consistence of a syrup, and muriatic acid be then poured into it, a precipitate appears which possesses the properties of

benzoic acid.

9. When an infusion of tannin is dropped into urine, a white precipitate appears, having the properties of the combination of taunin and albumen or gelatine. Their quantity in healthy urine is very small, often indeed not sensible. Cruickshanks found that the precipitate afforded by tannin in healthy urine amounted to 1-240th

part of the weight of the urine.

10. If urine be evaporated by a slow fire to the consistence of a thick syrup, it assumes a deep brown colour, and exhales a fetul ammoniacal odour. When allowed to cool, it concretes into a mass of crystals, composed of all the component paris of urine. If four times its weight of alcohol be poured into this mass, at intervals, and a slight heat be applied, the greatest part is dissolved. The alcohol which has acquired a brown colour is to be decanted off, and distilled in a retort in a sand heat till the mixture has boiled for some time and acquired the consistence of a syrup. By this time the whole of the alcohol has passed off, and the matter, on cooling, crystallizes in quadrangular plates, which intersect each other. This substance is urea, which composes 9-20ths of the urine, provided the watery part be excluded. It is this substance which characterises urine, and constitutes it what it is, and to which the greater part of the very singular phanomena of urine are to be ascribed.

11. According to Fourcroy and Vauquelin, the colour of urine depends upon the urea; the greater the proportion of urea the deeper the colour. But Proust has detected a resinous matter in urine similar to the resin of bile, and to this substance he ascribes the colour of urine,

12 If urine be slowly evaporated to the consistence of a syrup, a number of crystals make their appearance on its surface, these possess the properties of the muriate of

13. The saline residuum which remains after the separation of urea from crystallized urine by means of alcohol, has been long known by the names of fusible salt of urine, and microcosmic salt. When these salts are examined, they are found to have the properties of phosphates. The rhombordal prisms consist of phosphate of ammonia, united to a little phosphate of soda, the rectangular tables, on the contrary, are phosphate of soda united to a small quantity of phosphate of ammonia, urine then contains phosphate of soda, and phosphate of ammonia.

14. When urine is cautiously evaporated, a few cubic crystals are often deposited among the other salts, these crystals have the properties of muriate of ammonia.

15. When urine is boiled in a silver basin, it blackens the basin, and if the quantity of urine be large, small crusts of sulphuret of silver may be detached. Hence we see that urine contains sul-

stances:

1. Water.

2. Acetic acid.

3. Phosphate of lime.

4. Phosphate of magnesia,

5. Carbonic acid.

6. Carbonate of lime:

7. Uric acid. 8. Rosaic acid

9. Benzoic acid.

10. Albumen.

11. Urea. 12. Resin:

13. Muriate of soda.

14. Phosphate of soda. 15. Phosphate of ammonia.

16. Muriate of ammonia.

17. Sulphur.

No liquor in the human body, however pure, is so variable, in respect to quantity and quality, as the urine; for it varies,

1. In respect to age: in the fatus it is inodorous, insipid, and almost aqueous; but as the infant grows, it becomes more acrid and fetid; and in old age more particularly so.

2. In respect to drink: it is secreted in greater quantity, and of a more pale colour, from cold and copious draughts. nettle.

It becomes green from an infusion of Chinese tea, or the use of the pulp of Cassia.

3. In respect to food: from eating the heads of asparagus, or olives, it contracts a peculiar smell; from the fruit of the opuntia, it becomes red; and from f-sting turbid.

4. In resiect to medicines: from the exhibition of rhubarb root, it becomes yellow; and from turpentine a violet co-

5. In respect to the time of the year: in the winter the urine is more copious and aqueous; but in the summer, from the increased transpiration, it is more sparing, higher coloured, and so acrid that it sometimes becomes strangurious. The climate induces the same difference.

6. In respect of the muscular motion of the body: it is secreted more sparingly, and concentrated by motion; and is more copiously diluted, and rendered more crude

by rest.

7. In respect of the affection of the mind:

thus fright makes the urme pale.

Use. The urine is an excrementitous fluid, like lixivium, by which the human body is not only liberated from the superfluous water, but also from the superfluous salts, and animal earth; and is defended from corruption.

Lastly, the vis medicatrix natura sometimes eliminates many morbid and acrid substances with the urine; as may be ob-

served in fevers, dropsies, &c.

URINE, RETENTION OF. A want of Urine then contains the following sub- the ordinary secretion of urine. In retention of urine there is none secreted; in a suppression, the urine is secreted but cannot be voided.

Urine, suppression of. See Ischuria.

URINA See Urine.

Urinaculum. See Urachus.

URINARIA. (From urina, urine; so named from its diuretic qualities.) The herb dandelion See Turaxacum.

URINÆ ARDOR. See Dysuria.

Unocrisia. (From seov, urine, and serva, to judge.) The judgment formed of diseases by the inspection of urine.

URORRHEA. (From sgov, the urine, and eεω, to flow.) A discharge of the urine

through the eroded peringum.

The root of the plant URSINA RADIX. See Meum athamanticalled baldmoney.

UROSCOPIA. (From 850v, the urine, and σκοπεω, to inspect.) Inspection of urine, that a judgment of diseases may be made

from its appearance.

(Ab urendo; because it ex-URTICA. cites an itching and pustules like those produced by fire.) 1. The name of a genus of plants in the Linnaan system. Monoecia. Order, Tetrandria.

Utriculus.

The form of the uterus resembles that of sacrum; but, in the impregnated state, it becomes more oval, according to the degree of its distention. For the convenience of description, and for some practical purposes, the uterus is distinguised into three parts. The fundus, the body, the fundus, the lower the cervix, the space between them, the extent of which is undefined, the body. The uterns is about three inches in length, about two in breadth at the fundus, and one at the cervix. Its thickness is different at the fundus and cervix, being at the former usually rather less than half an inch, and at the latter somewhat more; and this thickness is preserved throughout pregnancy, chiefly by the enlargement of the veins and lymphatics; there being a smaller change in the size of the arteries But there is so great a variety in the size and dimensions of the uterus in different women, independent of the states of virginity, marriage, or is corrugated in a beautiful manner, but the ruge, or wrinkles, which are longitudithe fundus of which is smooth. In the intervals between the rugæ are small orifi-UNDEA. Muscus cranii humani. This ces, like those in the vagina, which dismoss, Lichen saxatilis of Lannzus, when charge a mucus, serving, besides other purposes, that of closing the os uters very curiously and perfectly during pregnancy. The subs ance of the uterus, which is very UTERARIA. (From uterus, the womb) firm, is composed of arteries, veins, lym-Med cines appropriated to diseases of the phatics, nerves, and muscular fibres, curiously interwoved and connected together by cellular membrane. The muscular

in their texture somewhat different from or reticulated order, whilst others have muscular fibres in other parts of the body, contended that there were no muscular The arteries of the uterus are the sperma- fibres whatever in the uterus. In the untic and hypogastric. The spermatic arteries impregnated uterus, when boiled for the arise from the anterior part of the aorta, a little below the emulgents, and sometimes from the emulgents. They pass over the psox muscles behind the peritonxum, enter between the two taming or duplicatures of the peritonaum which form the broad ligaments of the uterus, and proceed to the uterus, near the fundus of which they insinuate the mselves, giving branches in their passage to the ovaria and Fallopian tubes. The hypogastric arteries are on each side a considerable branch of the internal iliacs. They pass to the sides of the body of the uterus, sending off a number of smaller branches, which dip into its substance. Some branches also are reflected upwards to the fundus uteri, which anastomose with the spermatic arteries, and others are reflected downwards, supplying the vagina. The veins which reconduct the blood from the uterus are very numerous, and their size in the unimpregnated state is proportioned to that of the arteries; but their enlargement during pregnancy is such, that the orifices of some of them, when divided, will admit ev n of the end of a small finger. The veins anastomose in the manner of the arteries which they accompany out of the uterus, and then, having the same names with the arteries spermatic and hypogastric, the former proceeds to the vena cava on the right side, and on fimbriæ. The canal which passes through the left to the emulgent vein; and the latter to the internal iliac.

From the substance and surfaces of the uterns an infinite number of lymphatics arise, which follow the course of the hypogastric and spermatic blood-vessels. The first pass into the gland of the internal iliac plexus, and the other into the glands which are situated near the origin of the spermatic arteries. Of these Nuck first gave a

The uterus is supplied with nerves from the lower mesocolic plexus, and from two small flat circular ganglions, which are situated behind the rectum. These ganglions are joined by a number of small branches from the third and fourth sacral The ovaria derive their nerves from the renal plexus. By the great number of nerves these parts are rendered very irritable, but it is by those branches which the uterus receives from the intercostal, that the intimate consent between it and the peritonaum, and pass out of the pelvis various other parts is chiefly preserved. through the ring of the external oblique The muscular fibres of the uterus have been muscle to the groin, where the vessels subdescribed in a very different manner by divide into small branches, and terminate anatomists, some of whom have asserted at the mons veneris and contiguous parts. that its substance was chiefly muscular, From the insertion of these ligaments into

purpose of a more perfect examination. the former seems to be a true representation; and when the uterus is distended towards the latter part of pregnancy, these fibres are very thinly scattered; but they may be discovered in a circular direction, at the junction between the body and the cervix of the uterus, and surrounding the entrance of each Fallopian tube in a similar order. Yet it does not seem reasonable to attribute the time of labour to its muscular fibres only, if we are to judge of the power of a muscle by the number of fibres of which it is composed, unless it is presumed that those of the uterus are stronger than in common muscles. With respect to the glands of the uterus, none are discoverable dispersed through its substance upon the inner surface of the cervix; between the rugæ there are lacunæ which secrete mucus, and there are small follicles at the edge of the os uteri. These last are only observable in a state of pregnancy, when they are much enlarged. From the angles at the fundus of the uterus, two processes of an irregular round form originate, called, from the name of the first describer, the Fallopian tubes. They are about three inches in length, and, becoming smaller in their progress from the uterus, have an uneven, fringed termination, called the these tubes is extremely small at their origin, but it is gradually enlarged, and terminates with a patulous orifice, the diameter of which is about one third of an inch, surrounded by the fimbriæ. It is also lined by a very fine vascular membrane, formed into serpentine plicæ. Through this canal, the communication between the uterus and ovaria is preserved. The Fallopian tubes are wrapped in duplicatures of the peritonæum, which are called the broad ligaments of the uterus; but a portion of their extremities, thus folded, hangs loose on each side of the pelvis. From each lateral angle of the uterus, a little before and below the Fallopian tubes, the round ligaments arise, which are composed of arteries, veins, lymphatics, nerves, and a fibrous structure. These are connected together by cellular membrane, and the whole is much enlarged during pregnancy. They receive their outward covering from with fibres running in transverse, orbicular, the groin, the reason appears why that part

The use of the womb is for cause the enlargement is then chiefly at menstruation, conception, nutrition of the the fundus. If the uterus is but little enforced, pregnanced, because the enlargement is then chiefly at menstruation, conception, nutrition of the fœtus, and parturition. The uterus is lia-larged, or if it be enlarged beyond a ble to many diseases, the principal of certain time, it cannot well be retroverted; which are prolapsus uteri, procidentia uteri, hydatids, dropsy of the uterus or tympanites uteri, moles, ulceration, &c.

UTERUS, RETROVERSION OF. By the term retroversion, such a change of the position of the uterus is understood, that the fundus is turned backwards and downwards upon its cervix, between the vagina and rectum, and the os uteri is turned forwards to the pubis, and upwards in proportion to the descent of the fundus, so that, by an examination per vaginum, it cannot be felt, or not without difficulty, when the utcrus is retroverted. By the same examination there may also be perceived a large round tumour, occupying the inferior part of the cavity of the pelvis, and pressing the vagina towards the pubis. By an examination per anum, the same tumour may be felt, pressing the rectum to the hollow of the sacrum, and if both these examinations are made at the same time, we may readily discover that the tumour is confined between the vagina and rectum. Besides the knowledge of the retroversion which may be gained by these examinations, it is found to be accompanied with other very distinguishing symptoms. There is in every case, together with extreme pain, a suppression of urine; and by the continuance of this distention of the bladder the tumour formed by it in the abdomen often equals in size, and resembles in shape, the uterns in the sixth or seventh months of pregnancy; but it is necessary to observe, that the suppression of urine is frequently absolute only before thiaca. the retroversion of the uterus, or during the time it is retroverted; for when the retroversion is completed, there is often a discharge of urine, so as to prevent an in- Bears' whorts, or bear's bilberries, called

tions or diseases of the uterus are disturbed the fundus. If the uterus is but little en-larged, or if it be enlarged beyond a for, in the first case, should the cause of a retroversion exist, the weight at the fundus would be wanting to produce it; and in the latter the uterus would be raised above the projection of the sacrum, and supported by the spine.

UTRICARIA. (From uter, a bottle; so named from its appendages at the end of the leaves resembling bottles, to contain water.) A name of the nepanthes, or wonderful plant.

UTHICULUS. (Dim. of uter, a bottle; so

called from its shape.): The womb.
Uva. (Quasi uvida, from its juice.) An unripe grape. A tumour on the eye resembling a grape.

UVA GRUINA. Crane-berries. They are brought from New England, and are reckoned antiscorbutic.

UVA PASSA MAJOR. Passula major. The raisin. The dried fruit of the Vitis vinifera of Linnæus :- foliis lobatis sinuatis nudis. Raisins are prepared by immersing the fresh fruit into a solution of alkaline salt and soap-ley, made boiling hot, to which is added some olive-oil, and a small quantity of common salt, and afterwards drying them in the shade. They are used as agreeable, lubricating, acescent sweets in pectoral decoctions, and for obtunding the acrimony in other medicines, and rendering them grateful to the palate and stomach. They are directed in the decoctum hordei compositum tinctura sennæ, and tinctura cardamonii composita.

UVA PASSA MINOR. Passa corin-The currants The dried fruit of the vitis corinthica. Their virtues are similar to those of the uva passa major.

UVA URSI. Bear's whortle-berry. crease of the distention of the bladder, also vaccaria vaccinic. Trailing arbutus, or bear-berry. Arbutus uva ursi of Linnæus: -canlibus procumbentibus, foliis integerrimis. This plant, though employed by the ancients in several diseases, requiring adstringent medicines, had almost entirely fallen into disuse until the middle of the present century, when it first drew the attention of physicians as a useful remedy in calculous and nephritic complaints, which diseases it appears to relieve by its adstringent qualities

UVEA. (From uva, an unripe grape.) The posterior lamina of the iris; so called because, in beasts, which the ancients chiefly dissected, it is of the colour of un-

lumella, Cion. Gargareon. Columna oris. more adstringent remedies.

Gurgulio interseptum. The small conical fleshy substance hanging in the middle of the velum pendulum palati, over the root of the tongue. It is composed of the common membrane of the mouth, and a small muscle resembling a worm which arises from the union of the palatine bone, and descends to the tip of the uvula. It was called Pulato staphilinus by Douglas, and Staphilinus epistaphilinus by Winslow. By its contraction the uvula is raised up.

UVULARIA. (From uvula, because it cured diseases of the uvula.) The plant which bears this epithet in some pharmacopaias is the Ruscus hypoglossum of Linripe grapes.

UVULA (Dim. of uva, a grape.)

VAGINA. A sheath. Vagina uteri. That canal which leads from the pudendum or external brifice to the uterus, is called the vagina. It is somewhat of a conical form, with the narrowest part downwards, and is described as being five or six inches in length, and about two in diameter. But it would be more proper to say, that it is capable of being extended to those dimensions; for in its common state, the os uteri is seldom found to be more than three inches from the external orifice, and the vagina is contracted as well as shortened. The vagina is composed of two coats, the first or innermost of which is villous, interspersed with many exerctory ducts, and such an abbreviation and contraction as contracted into plica, or small transverse render it unfit for the uses for which it was folds, particularly at the fore and back designed: secondly, a cohesion of the sides part, but, by child-bearing these are les- in consequence of preceding ulceration:

sened or obliterated. The second coat is composed of a firm membrane, in which muscular fibres are not distinctly observable, but which are endowed, to a certain degree, with contractile powers like a This is surrounded by cellular muscle. membrane, which connects it to the neighbouring parts. A portion of the upper and posterior part of the vagina is also covered by the peritonæum. The entrance of the vagina is constricted by muscular fibres, originating from the rami of the pubis, which run on each side of the pudendum, surrounding the posterior part, and executing an equivalent office, though they cannot be said to form a true sphincter.

The upper part of the vagina is connect. not in a straight line, so as to render the cavity of the uterus a continuation of that of the vagina. For the latter stretches beyond the former, and, being joined to the cervix, is reflected over the os uteri, which, by this mode of union, is suspended with protuberan lips in the vagina, and permitted to change its position in various ways and directions. When therefore these parts are distended and unfolded at the time of labour, they are continued into each other, and there is no part which can properly be considered as the precise begin ing of the uterus or termination of the vagina.

The diseases of the vagina are, first,

thirdly, cicatrices after an ulceration of the cast off wholly or partially. An ulcerated parts: fourthly, excrescences: fifthly, surface being thus left, when the disposi-fluor albus This abbreviation and contion to heal has taken place, cicatrices traction of the vagina, which usually accompany each other, are produced by cording to the depth and extent of the original defective formation, and they are ulceration; and there being no counteracseldom discovered before the time of mar- tion to the contractile state of the parts, riage, the consummation of which they the dimensions of the vagina become much sometimes prevent. VARI See Jonthi.

VARIA. (From varius, changeable.) The small-pox, also small red pimples in the face.

VARICELLA. (Dim. of varie, the small-pox; so called from its being changeable.) Variola lymphatica. The Chickenpox. A genus of disease in the class pyrexix and order exauthemata of Cullen; known by moderate synocha; pimples bearing some resemblance to the small-pox, quickly forming pustules, which contain a fluid matter, and after three or four days from their first appearance, desquamate.

VARICOCELE. (From varia, a distended vein, and xnhh, a tumour.) A swelling of the veins of the scrotum, or spermatic cord; hence it is divided into the scrotal varicocele, which is known by the appearance of livid and tumid veins on the scrotum; and varicocele of the spermatic cord, known by feeling hard vermiform vessels in the course of the spermatic cord.

Varicocele mostly arises from excessive walking, running, jumping, wearing of trusses, and the like, producing at first a slight uneasiness in the part, which if not remedied, continues advancing towards

the loins.

VARIOLA. (From varius, changing colour, because it disfigures the skin.) The small pox. A genus of disease in the class pyrexia and order exanthemata of Cullen; distinguished by synocha; eruption of red pimples on the third day, which on the eighth day contain pus, and drying, fall off in crusts

It is a disease of a very contagious nature, supposed to have been introduced into Europe from Arabia, and in which there arises a fever, that is succeeded by a number of little inflammations in the skin, which proceed to suppuration, the matter formed thereby being capable of produ-

cing the disorder in another person. It number and size for three or four longer, makes its attack on people of all ages, but the young of both sexes are more hanle to it than those who are much advanced in life; and it may prevail at all the seasons of the year, but in general is most prevalent in the spring and summer.

The small-pox is distinguished into the distinct and confluent, implying that in the former, the eruptions are perfectly separate from each other, and that in the latter,

they run much into one another.

Both species are produced either by breathing air impregnated with the effluvia arising from the body of those who labour under the disease, or by the introduction of a small quantity of the variolous matter into the habit by inoculation; and it is probable that the difference of the smallpox is not owing to any difference in the contagion, but depends on the state of the person to whom it is applied, or on certain circumstances concurring with the application of it.

A variety of opinions have been entertained respecting the effect of the variolous infection on the feetus in the utero; a sufficient number of instances, however, has been recorded, to ascertain that the disease may be communicated from the mother to the child. In some cases, the body of the child, at its birth, has been covered with pustules, and the nature of the disease has been most satisfactorily ascertained by inoculating with matter taken from the pustules In other cases, there has been no appearance of the disease at the time of the birth, but an eruption and other symptoms of the disease have appeared so early, as to ascertain that the infection must have been received previously to the removal of the child from the aterus.

Four different states, or stages, are to be observed in the small-pox : first, the febrile; second, the emprive; third, the maturative; and fourth, that of the declina-tion or scabbing. When the disease has arisen naturally, and is of the distinct kind, the eruption is commonly preceded by a redness in the eyes, soreness in the throat, pains in the head, back, and loins, weariness and faintness, alternate fits of chillness and heat, thirst, nausea, inclination to voma, and a quick pulse.

In some instances these symptoms prevail in a high digree, and in others they are very moderate and triffing. In very young children, startings and convulsion are apt to take place a short time previous to the ppearance of the emption, always giving great alarm to those not conversant with the frequency of the occurrence.

About the third or fourth day from the first scizure, the eruption shews itself in little red spots on the face, neck, and breast, and these continue to increase in at the end of which time, they are to be observed dispersed over several parts of the body.

If the pustules are not very numerous, the febrile symptoms will generally go off on the appearance of the eruption, or they will become very moderate. It sometimes happens, that a number of little spots of an erysipelatous nature are interspersed amongst the pustules; but these generally go in again, as soon as the suppuration commences, which is usually about the fifth or sixth day, at which period, a small vesicle, containing an almost colourless fluid, may be observed upon the top of each pimple. Should the pustules be perfectly distinct and separate from each other, the suppuration will probably be completed about the eighth or ninth day, and they will then be filled with a thick yellow matter; but should they run much into each other, it will not be completed till some days later.

When the pustules are very thick and numerous on the face, it is apt about this time to become much swelled, and the eyelids to be closed up, previous to which, there usually arises a hourseness, and difficulty of swallowing, accompanied with a considerable discharge of viscid saliva. About the eleventh day, the swelling of the face usually subsides, together with the affection of the fauces, and is succeeded by the same in the hands and feet, after which the pustules break, and discharge their contents; and then b. coming dry, they fall in crusts, leaving the skin which they covered of a brown red colour, which appearance continues for many days. those cases where the pustules are large, and are late in becoming dry and falling off, they are very ap to leave pits behind them; but where they are small, suppurate quickly, and are few in number, they neither leave any marks behind them, nor do they occasion much affection of the sys-

In the confluent small pox, the fever which precedes the eruption is much more violent than in the distinct, bein, attended usually with great anxiety, heat, thirst, nausea, vomiting, and a frequent and contracted pulse, and often with coma or de-In infants, convulsive fits are apt to occur, which either prove fatal before any eruption appears, or they usher in a malignant species of the discuse.

The eruption usually makes its appearance about the third day, being frequently preceded or attended with a rusy efflorescence, similar to what takes place in the measles; but the fever, although it suffers some slight remission on the coming out of the eruption, does not go off as in he distinct kind; on the contrary, it becomes increased after the fifth or sixth day, and

continues considerably throughout the re- or approaches nearly in its nature to that mainder of he disease.

As the emption advances, the face being thickly beset with pustules, becomes degree of which is ever in proportion to the very much swelled, the eyelids are closed violence and permanence of the fever, the up, so as to deprive the patient of sight, number of postules on the face, and the and a gentle's divation ensues, which, to-disposition to putrescency which prevails. wards the eleventh day, is so viscid as to be spit up with great difficulty. In children, a diarrhœa usually attends this stage of the disease instead of a salivation, which is to be met with only in adults. The vesicles on the top of the pimples are to be perceived sooner in the confluent small pox than in the distinct; but they never rise to an eminence, being usually flatted in; neither do they arrive to proper suppuration, as the fluid contained in them, instead of becoming yellow, turns to a brown colour.

About the tenth or eleventh day, the swelling of the face usually subsides, and then the hands and feet begin to puff up and swell, and about the same time the vesicles break, and pour out a liquor that forms into brown or black crusts, which, upon falling off, leave deep pits behind them that continue for life; and where the pustules have run much into each other, they then disfigure and scar the face very

considerably.

Sometimes it happens that a putrescency of the fluids takes place at an early period of the disease, and shews itself in livid spots interspersed amongst the pustules, and by a discharge of blood by urine, stool, and from various parts of the body.

In the confluent small-pox, the fever, which, perhaps, had suffered some slight remission from the time the eruption made its appearance to that of maturation, is often renewed with considerable violence at this last-mentioned period, which is what is called the secondary fever, and this is the most dangerous stage of the disease. It has been observed, even amongst the vulgar, that the small pox is apt to appear immediately before or after the prevalence of the measles. Another curious observation has been made relating to the symptoms of these complaints, namely, that if, while a patient labours under the stances, the lungs have often a darker apsmall pox, he is seized with the measles, the course of the former is retarded till ous than usual. When no inflammatory the eruption of the measles is finished, affection has supervened, they are most The measles appear, for instance, on the second day of the eruption of small-pox, the progress of this ceases, till he measles terminate by desquamation, and then it goes on in the usual way. Several cases are, however, recorded in the Medical and Physical Journal, as likewise in the third volume of the Medical Commentaries, in which a concurrence of the small-pox and measles took place without the progress of which was recommended to the world by the former being retarded. The distinct Dr. Jenner, in the year 1798, as a substismall-pox is not attended with canger, ture for the small-pox. This, which oriexcept when it attacks pregnant women, ginates from the grease in the horse's heel,

When there is a great endency this way, the disease usually proves fatal between the eighth and eleventh day, but, in some cases, death is protracted till the fourteenth or sixteenth. The confluent small. pox, although it may not prove immediate. ly mortal, is very apt to induce various

morbid affections.

Both kinds of small-pox leave behind them a predisposition to inflammatory complaints, particularly to ophthalmia and visceral inflammations, but more especially of the thorax; and they not unfrequently excite scrophula into action which mi ht otherwise have laid dormant in the system.

The regular swelling of the hands and feet upon that of the face subsiding, and its continuance for the due time, may be re-

garded in a favourable light.

The dissections which have been made of confluent small pox, have never discovered any pustoles internally on the viscera. From them it also appears that variolous pustules never attack the cavities of the body, except those to which the air has free access, as the nose, mouth, trachea, the larger branches of the bronchia, and the outermost part of the meatus audiorius. In cases of prolapsus ani, they likewise frequently attack that part of the gut which is exposed to the air. They have usually shewn the same morbid appearances inwardly, as are met with in putrid fever, where the disease has been of the mahgnant kind. Where the febrile symptoms have run high, and the head has been much affect d with coma or debrium, the vessels of the brain appear, on removing the cranium and dura mater, more turgid, and filled with a darker coloured blood than usual, and a greater quantity of serous fluid is found, particularly towards the base of the brain. Under similar circumpearance, and their moisture is more copiusually found.

VARIOLA VACCINA. The cow-pox. Any pustulous disease affecting the cow, may be called the cow-pox: whether it arises from an over-distention of the udder, in consequence of a neglect in milking the cow, or from the sting of an insect, or any other cause. But the species which claims our particular attention, is that is called the genuine cow-pox; all other who contracted it by milking were ren-

unspeakable benefits to mankind, derives its origin from this humble source, how- which the disease was excited in the huever it may mortify human pride, or medi- man subject; one person, who caught the cal vanity, is confirmed by the observa- disease while the virus was in an active tions and experiments of competent judges. state, is rendered secure from variolous For proofs of this assertion, the reader may contagion; while another who received consult the works of Dr Jenner; the Me- the infection of the cow-pox when it had diral and Physical Journal; and a treatise undergone a decomposition, is still suson the subject by Dr. Loy, of which an analys's is given in the Annals of Medicine for of the prevention, the value of which is the year 1801; and Mr. Ring's work on this beyond all calculation, is probably the disease, which contains the whole mass of evidence that has appeared concerning it.

The genuine cow-pox appears on the teats of the cow, in the form of vesicles, of a blue colour approaching to livid. These vesicles are elevated at the margin, and depressed at the centre. They are surthey contain is impid. The animals are indisposed; and the secretion of milk is lessened. Solutions of the sulphats of zinc and copper are a speedy remedy for these pustules; otherwise they degenerate into ulcers, which are extremely troublesome. It must, however, be recollected, that much of the obstinacy attending these cases is owing to the friction of the pustules, in consequence of milking. It is probable, that a solution of the superacetare of lead would be preferable to irritating applications.

Similar effects are produced in the hands of the milkers, attended with febrile symptoms, and sometimes with tumours in the Other parts, where the cuticle is abrided, or which are naturally destitute of that defence, are also hable to the same affection, provided active matter is applied. It even appears that, in some instances, pustules have been produced by the application of vaccine virus to the sound cuticle. One case of this kind may be found in a letter from Dr. Fowler, of Salisbury, to Dr. Pearson, published in the first work of Dr. Pearson on this subject.

The spurious cow-pox is white: and another criterion is, that both in the brute animal and in the human subject, when infected with the casual cow-pox, the sores occasioned by the genuine species are more difficult to heal, than those which are occasioned by the spurious kindof the utmost importance to distinguish the genuine from the spurious sort, which is also in some degree infectious; since a want of such discrimination would cause the teats of the cow. He now concludes, an idea of security against the small-pox, that it is perfect when it excites the gewhich might prove delusive.

the first importance, relative to the ge-ferred to the latter animal, the nipples of nuine cow-pox uself. It had frequently which furnish a more obvious and a more been observed, that when this disorder abundant source of this inestimable fluid prevailed in a farm, some of the persons than its original element the horse.

dered insus eptible of the small pox, while That the vaccine fluid, fraught with such others continued liable to that infection. This is owing to the different periods at ceptible of the small pox. This uncertainty reason why it was not before introduced into practice.

From the violent opposition which vaccine moculation has niet with, in consequence of certain apparent failures in the casual way, it may be doubted whether the public would ever have adopted the practice, had not this fallacy been detected by Dr Jenner. To him also we are indebted for another discovery of the first importance, namely, that the pustule excited in the human subject by vaccine matter, yields a fluid of a similar nature with that which was inserted. This experiment, so essential to the general propagation of the practice, and so happy in its result, was never before at empted. It was reserved to crown the labours of Dr Jenner.

A considerable number of instances are on record, to prove that farriers and others who receive infection from the heel of a horse, are either partly or totally deprived of the susceptibility of the small-pox. When Dr. Jenner first published an account of his discoveries, this point was enveloped in some degree of obscurity. He then conceived, that the matt r of grease was an imperfect preservative against the small-pox. This opinion was founded on the following circumstance: It had been remarked, that farriers e ther wholly escaped the small-pox, or had that distemper in a milder manner than other people. This, however, is easily reconcileable to reason, if we only suppose, that in some cases the infection is communicated when the virus possesses all its prophylactic virtue; and in others, when its specific q ality is in some measure lost.

This variation in the effects produced by the virus of the horse, inclined Dr. Jenner to believe that it was modified, and underwent some peculiar alteration in nuine disease in the cow; yet a considerabe Dr. Jenner has elucidated one point of advantage is derived from its being trans-

This theory, that the preservative time submitted to that infection in the against variolous contagion is perfect when it issues from the fountain-head, and comes immediately from the hands of Nature, is consonant with reason, and consistent with analogy Thus one obstacle more to the universal adoption of the practice is removed

Another point respecting vaccine inoculation, which has been much controverted, is the permanency of its effect. Instances have been known where persons have escaped the small-pox for a number of years, and yet have ultimately proved not eruptions. When such attend vaccine insusceptible of its infection. When such persons had previously undergone the vaccine disease, their apparent security was erroneously ascribed to that cause; but we have not even a shadow of proof, that the cow-pox possesses in the least degree the property of a temporary prophyl ctic, since it appears not even to retard the eruption of the small-pox. where previous infection has been re-

By this remark, it is not meant to be asserted, that it never supercedes or modifies the small pox, for we have great reason to believe that such beneficial effects often flow from vaccination; but where an eruption of the small-pox actually takes place after vaccine inoculation, the two diseases frequently co-exist, without retarding each other in the smallest degree. It is therefore contrary to all reason and analogy, to consider the cow-pox as a mere temporary preservative: it is nothing less than a perfect and permanent security against that terrible disease.

A number of cases are recorded by Dr. Jenner, and other authors who have written on this subject, in which persons who had received the cow-pox by casual infection, twenty, thirty, forty, and fifty years before, still continued insusceptible of variolous contagion, in whatever form

it was applied.

As the cow-pox destroys the susceptibility of the small-pox, so the small-pox destroys that of the cow-pox. To this general rule, however, a few exceptions are said to have occurred. Certain it is, that a pustule has now and then been excited by the insertion of vaccine virus, in those who have had the small-pox, and that this pustule has been known to yield the genuing virus; but it is not equally certain that the pustule has been perfect in all respects. Possibly it may have been defective in point of size or duration; in respect to its areola, or the limpidity of its contents. That such a pustule has, in some instances, yielded effectual virus, is admitted; but this is no more than what has often happened, in cases where persons who have had the small-pox are a second traced to some other cause. We have in-

same form.

The artificial cow-pox in the human subject is much milder than the casual disease; and incomparably milder than the small-pox, even under the form of inoculation. It neither requires medicine nor regimen; it may be practised at any season of the year; and, not being infectious by effluvia, one person may be inoculated without endangering the life of another.

This affection produces no pustulous inoculation, they are owing to some adventitious cause, such as the small pox, which it is well known may co-exist with the cow-pox. The vaccine vesicle is confined to the parts where matter is inserted; it is therefore entirely a local and an inoculated dise; se. Nevertheless it is certain, that eruptions of other kinds in some instances attend vaccine inoculation; such as a nettle rash, or an eruption resembling a tooth rash, but rather larger than what is commonly called by that name

Among other singularities attending the cow-pox, the mildness of the disease, under the form of inoculation, has been urged as an argument against the practice, the cause appearing to ordinary comprehensions, inadeq ate to the effect. This, it must be allowed, is the best apology that can be offered for scepticism on that point; but it will weigh but little when put into the scale against actual observation, and incontroverible fact. The efficacy of the cow-pox as a safeguard against the small pox, rests, perhaps, on more extensive evidence, and a more solid foundation, than any-other axiom in the whole circle of medical science can boast,

That the cow-pox is not infectious by effluvia, is naturally concluded from its never being communicated from one person to another in the dairies; where the disease is casual, and appears under its worst form. The same inference may be drawn from its never spreading in a family, when only one person is inoculated a' a time. To confirm this proposition more fully, the vaccine pustules have been ruptured, and persons who have never had the disorder have been suffered to inhale the effluvia several times a day, but to no purpose. This is no more than might be expected, in an affection where the pustulous appearance on the surface of the body is nearly

As to the constitutional indisposition, it is seldom considerable, unless there is a complication of this with some other distemper; and whenever any unfavourable symptoms appear they may in general be

> Instances have been known, where the It might have been trivial; it might have been transient; yet it might have been There is, however, greater

phænomena of the local affection; both on account of the uncertainty of success in the pustule, as a prophylactic; and the greater

probability of tedious ulceration.

If there is room for the least doubt of the sufficiency of the first inoculation, a second ought to be performed without delay. This, if unnecessary, is seldom attended with inconvenience, and never with danger. Either no effect is produced, or a slight festering, which terminates in a few days. An exception occurs, but rarely, where a spurious, or, perhaps, even a genuine pustule, takes place, in those persons who are known to have had the cow-pox or the small-pox already; but this cannot be the least cause of alarin to any one who knows the benign character of the distemper.

Various topical applications, both stimulant and sedative, have been recommended, in order to allay the violence of inflammation. If the operation for the insertion of matter is not unnecessarily severe, nor the pustule irritated by friction or pressure, or other violence, no such applica-Nevertheless, if tions are necessary. either the anxiety of the professional man, or the importunity of a tender parent, should demand a deviation from this general rule, any of the following remedies may be had recourse to. The pustule may be touched with very diluted sulphuric acid; which should be permitted to remain on the part half a minute, and then be washed off with a sponge dipped in cold water. This has been ignorantly, or artfully, called an escharotic; but any one who tries the application will soon discover, that its operation is mild and harmless.

To avoid cavil and misrepresentation, it is better to apply a saturnine lotion; either made with aq. litharg. comp. or cerusa acetata; compresses, dipped in such a lotion, may be applied at any time when inflammation runs high, and renewed as

occasion requires.

If the pustule should chance to be broken, a drop of aq. litharg. acet. undiluted, may be applied as an exsiceant; but if ulceration threatens to become obstinate, or extensive, a mild cataplasm is the best resource. In case the ulceration is only superficial, and not attended with immoderate inflammation, a bit of any adhesive plaister, spread on linen, will prove the most convenient dressing, and seldom fail of success. It will, in general, be unnecessary to renew it oftener than every other day.

These minute observations no one will despise, unless there be any person so ignorant as not to know that the care of

to be paid to the progress, and to all the medical practitioner in vaccine inoculation; and that nothing disgusts the public so much against the practice, as a sore arm, and the ill consequences which, tom a neglect of that symptom, too often ensue.

> When fluid virus cannot be procured. it is necessary to be can ious how it is preserved in a dry state. The most improper mode is that of keeping it on a lancet; for the metal quickly rusts, and the vaccine matter becomes decomposed. This method, however, is as likely to succeed as any, when the matter is no to be kept above two or three d ys. If the virus be takenon glass, care must be taken not to dilute it much; otherwise it will in

all probability fail.

Cotton thread is a very commodious vehicle. If it is intended to be sent to any considerable distance, it ought to be repeatedly dipped in the virus. No particular caution is necessary with regard to the exclusion of air; nevertheless, as it can be done with so little trouble, and is more satisfactory to those who receive the matter, it is better to comply with the practice. On this account it may be enclosed in a glass tube, or in a tobacco-pipe scaled at each end, or between two square bits of glass, which may, if necessary, be also charged with the matter, and wrapped in gold-beater's skin.

Nothing is more destructive to the efficacy of cow-pox matter than heat: on this account it must not be dried near the fire, nor kept in a warm place. The advantage of inserting it in a fluid state is so great, that it is to be wished every practitioner would endeavour to keep a constant supply for his own use, by inoculating his patients in succession, at such periods as are most likely to answer that purpose.

The rapidity with which this practice now spreads in various parts of the globe, justifies our cherishing a hope, that it will ere long exanguish that most dreadful pestilence, and perpetual bane of human

felicity, the small-pox.

VASTUS EXTERNUS. (Vastus, so called from its size ) A large, thick, and fleshy muscle situated on the outer side of the thigh: it arises, by a broad thick tendon, from the lower and anterior part of the great trochanter, and upper part of the linea asperia; it I kewise adheres by fleshy fibres, to the whole outer edge of that rough line. Its fibres descend obliquely forwards, and after it has run four or five inches downwards, we find it adhering to the anterior surface and outer side of the cruræns, with which it continues to be connected to the lower part of the thigh, where we see it terminating in a broad tendon, which is inserted into the upper part of the patella laterally, and sends off an aponeurosis that adheres to the head of the libia, and is continued down the leg

This muscle, VASTUS INTERNUS. which is less considerable than the vastus externus, is situated at the inner side of the thigh, being separated from it by the

rectus.

It arises tendinous and fleshy from between the fore-part of the os femoris, and the root of the lesser trochanter, below the insertion of the psoas magicus, and the iliacus internus; and from all the inner side of the linea aspera. Like the vastus externus it is connected with the cruræus, but it continues longer fleshy than that muscle. A little above the knee we see its outer edge uniting with the inner edge of the rectus, after which it is inserted tendinous into the upper part and inner side of the patella, sending off an aponeurosis which adheres to the upper part of the tibia.

(Vena, from renio, to come, because the blood comes through it ) Veins are long membranous canals, which contiqually become wider, do not pulsate, and which unites with the external and inreturn the blood from the arteries to the heart. All veins originate from the extre- vein which brings the blood from the mities of arteries only, by anastomosis, and vertebral sinuses; it receives also the terminate in the annicles of the hearn; e.g. blood from the mediastinal, pericardiac, the vena cava in the right, and the pul- diaphragmatic, thymic, internal mammary monary voins in the left auricle. They are and largugeal veins, and then unites with composed, like arteries, of three tunies or its fellow, to form the vena cava superior, coats, which are much more slender than or, as it is sometimes called, vena cava in the ar cries, and are supplied with semi- descendens. lunar membranes or folds called valves.

The blood is returned from every part of the body, except the lungs, into the right auricle, from three sources:

1. The vena cava superior, which brings it from the head, neck, thorax, and supe-

rior extremities.

2. The vena cava inferior, from the abdomen and inferior extremities.

3. The coronary vein receives it from the coronary arteries of the heart.

1. The vena cava superior. This vein terminates in the superior part of the right auricle, into which it evacuates the blood, from the right and left subclavian veins, and the vena azygos. The right and left sub lavian veins receive the blood from the head and upper extremities, in the following manner. The veins of the fin-

from the digital arteries, and empty it into, The cephalic of the thumb, which runs on the back of the hand along the thumb, and evacuates itself into the external ra-

gers, called digitals, receive their blood

dial.

The salvatella, which runs along the little finger, unites with the former, and empties its blood into the internal and external cubital veins. At the bend of the fore arm are three veins, called the great cephalic, the basilic, and the median.

The great cephalic runs along the superior part of the fore-arm, and receives the

blood from the external rad al

The basilic ascends on the under side, and receives the blood from the external and internal cubital veins, and some branches which accompany the brachial artery, called venæ satellitum.

The median is situated in the middle of the tore-arm, and arises from the union of several branches. These three voins all unite above the bend of the arm, and

(Quasi herbena, a name edly moistened with water; and at length, of distinction for all herbs used in sacred a crust of verdigris is formed, which is rites.) 1. The name of a genus of plants scraped off by a knife, is put into bags, in the Linnman system. Class, Decandria. and dried by exposure of these to the air and sun. It is of a green colour, with a

In this preparation the copper is oxy-

\* 5 Q

portion of oxyde as it can retain in solution, are dissolved, and the remaining oxyde is left undissolved. From this analysis of it by the action of water, Proust inferred that it consists of 43 of acetate of copper, 27 of black oxyde of copper, and 30 of water, this water not being accidental, but existing in it in intimate combination.

Verdigris is used as a pigment in some of the processes of dyeing, and in surgery it is externally applied as a mild detergent in cleansing foul ulcers, or other open wounds. On account of its virulent properties, it ought not to be used as a medicine without professional advice; and in case any portion of this poison be accidentally swallowed, emetics should be first given, and afterwards cold water gently alkalized ought to be drank in abundance.

These oblique processes are arheaths, as that of Hampstead, flowering in June and July. This plant was formerly used as a pectoral against coughs and asthmatic affections, but it is now justly forgotten.

VERRICULARIS TUNICA. The retina of the

VERTEBRÆ. (From verto, to turn.) The spine is a long bony column, which extends from the head to the lower part of the trunk, and is composed of irregular bones which are called vertebræ.

The spine may be considered as being composed of two irregular pyramids, which are united to each other in that part of the loins where the last of the lumbar vertebræ is united to the os sacrum.

The vertebræ, which form the upper and longest pyramid, are called true vertebra; and those which compose the lower pyra. mid, or the os sacrum and coccyx, are termed false vertebra, because they do not in every thing resemble the others, and particularly because, in the adult state, they become perfectly immoveable, while the upper ones continue to be capable of motion. For it is upon the bones of the spine that the body turns, and their name has its derivation from the Latin verb verto, to turn, as observed above.

The true vertebræ, from their situations with respect to the neck, back, and loins. are divided into three classes, of cervical, dorsal, and lumbar vertebræ. We will first consider the general structure of all these, and then separately describe their

different classes.

In each of the vertebræ, as in other

cavity of the spine.

Each vertebra has commonly seven pro-VERMIFORM PROCESS. Protuberan- cesses. The first of these is the spinous process, which is placed at the back part spine to the whole of this bony canal, Two others are called transverse processes, from their situation with respect to the (Vermifuga, from ver- spine, and are placed on each side of the are called oblique processes, are much smaller than the other three. There are VERMIS MORDICANS. Vermis repens. A two of these on the upper and two on the lower part of each vertebra, rising from near the basis of the transverse processes. VERONICA. 1. The name of a genus They are sometimes called articular proof plants in the Linnaan system. Class, cesses, because they are articulated with Diandria. Order, Monogynia. Speedwell. each other; that is, the two superior pro-2. The pharmacopæial name of the Ve- cesses of one vertebra are articulated with Thea Germanica. Betonica the two inferior processes of the vertebra ticulated to each other by a species of ginglimus, and each process is covered at its articulation with cartifage.

There is in every vertebra, between its body and apophyses, a foramen, large enough to admit a finger. These foramina correspond with each other through all the vertebrz, and form a long bony conduit, for the lodgment of the spinal marrow.

Besides this great hole, there are four notches on each side of every vertebra, between the oblique processes and the body of the vertebra. Two of these notches are at the upper, and two at the lower part of the bone. Each of the inferior notches, meeting with one of the superior notches of the vertebra below it, forms a foramen; whilst the superior in a longitudinal direction, is extended notehes do the same with the inferior over the back part of the bodies of the notelies of the vertebra above it. These vertebræ, where they help to form the four foramina form passages for blood ves- eavity of the spine, and reaches from the sels, and for the nerves that pass out of the foramen magnum of the occipital bone to

The vertebræ are united together by means of a substance, compressible like the vertebræ diminish in density and firmcork, which forms a kind of partition ness of texture, in proportion as they between the several vertebræ. This inter- increase in size, so that the lower vertevertebral substance seems, in the fœtus, bræ, though larger, are not so heavy in to approach nearly to the nature of liga- proportion as those above them. In conments; in the adult it has a great resem- sequence of this mode of structure, the blance to eartilage. When cut horizon- size of the vertebræ is increased without tally, it appears to consist of concentrical adding to their weight; and this is an curved fibres, externally it is firmest object of no little importance, in a part of and hardest; internally it becomes thin the body, which, besides flexibility and ner and softer, till at length, in the een- suppleness, seems to require lightness as tre, we find it in the form of a mucous sub- one of its essential properties. stance, which facilitates the motions of the

Genga, an Italian anatomist, long ago observed, that the change which takes place in these intervertebral eartilages, (as they are usually called) in advanced life, oceasions the decrease in stature, and portions, which form the foramen for the the stooping forwards, which are usually medulla spinalis. The oblique processes to be observed in old people. The earti- are at that time complete, and the translages then become shrivelled, and eonse- verse processes beginning to be formed; but quently lose, in a great measure, their the spinous processes are totally wanting. elasticity. But, besides this gradual age and size of the subject; in tall, young people, it will be nearly an inch; but in older, or shorter persons, it will be less considerable.

Besides the connexion of the several vertebræ, by means of these cartilages, there are likewise many strong ligaments, which unite the bones of the spine to each external ligaments, we observe one which of which, like the external one, are spread part of this anterior portion is concave.

the os sacrum.

We may venture to remark, that all

In the fœtus, at the ordinary time of birth, each vertebra is found to be composed of three bony pieces, connected by cartilages which afterwards ossify of these pieces is the body of the bone: the other two are the posterior and lateral

The cervical vertebra, are seven in effect of old age, these cartilages are number, their bodies are smaller and of a subject to a temporary diminution, from firmer texture than the other bones of the weight of the body in an erect posture, so that people who have been long these vertebræ are shorn, and forked for standing, or who have earried a consider- the lodgment of museles; and, at the able weight, are found to be shorter than bottom of each of these processes, there is when they have been long in bed. Hence a foramen, for the passage of the cervical we are taller in the morning than at night. artery and vein. The spinous process of This fact, though seemingly obvious, was each of these vertebræ is likewise shorter not ascertained till of late years. The than the other vertebræ, and forked at its difference in such cases depends on the extremity; by which means it allows a more convenient insertion to the muscles of the neck. Their oblique processes are more deserving of that name than either those of the dorsal or lumbar vertebræ. The uppermost of these processes are slightly concave, and the lowermost slightly convex. This may suffice for a general description of these vertebra; other. Some of these ligaments are ex-ternal, and others internal. Among the serve to be spoken of more particularly. The first, which is called Atlas, from its is common to all the vertebræ, extending, supporting the head, differs from all the in a longitudinal direction, from the fore other vertebræ of the spine. It forms a part of the body of the second vertebra kind of bony ring, which may be divided of the neck, over all the other vertebra, into its anterior and posterior arches, and and becoming broader as it descends to- its lateral portions. Of these, the anterior wards the os sacrum, where it becomes arch is the smallest and flattest; at the thinner, and gradually disappears. This middle of its convex fore part we observe external longitudinal ligament, if we may a small tubercle which is here what the so call it, is strengthened by other shorter body is in the other vertebræ. To this ligamentous fibres, which pass from one tubercle a ligament is attached, which vertebra to another, thoughout the whole helps to strengthen the articulation of the spine. The internal ligament, the fibres spine with the os occipitis. The back

VIS PLASTICA. That facility of formation which spontaneously operates in

anımals.

VIS A TERGO. Any impulsive power, VIS VITÆ The natural power of the animal machine in preserving life.

VISCUM. Mistletoe. Viscum album of This singular parasitical plant Linnæus. most commonly grows on apple-trees, also on the pear, hawthorn, service, oak, hasel, maple, ash, lime-tree, willow, elm, horn-beam, &c. It is supposed to be propagated by birds, especially by the field-fare and thrush, which feed upon its berries, the seeds of which pass through the bow-els unchanged; and along with the excrement adhere to the branches of trees where they vegetate.

The mistletoe of the oak has, from the times of the ancient druids, been always preferred to that produced on other trees; but it is now well known that the viscus quercus differs in no respect from others.

This plant is the 13 of the Greeks, and was in former times thought to possess many medicinal virtues; however, we learn but little concerning its efficacy from the ancient writers on the materia medica, nor will it be deemed necessary to state the extraordinary powers ascribed to the mistletoe by the crafty designs of druidical knavery. Both the leaves and branches of the plant have very little smell, and a very weak taste of the nauseous kind. In distillation they impregnate water with their faint unpleasant smell, but yield no essential oil. Extracts, made from them nium.

by water, are bitterish, roughish, and subVIRUS. A synonym of contagion. See saline. The spirituous extracts of the wood has the greatest austerity, and that of the leaves the greatest bitterness. berries abound with an extremely tenacious and most ungrateful sweet mucilage.

aphoretic compound exhibited in the cure a continued ligament from its strength; of dysenteries arising from checked perspiration.

VITRUM HYPOCLEPTICUM. A funnel to

separate oil from water.

VOICE. Vox. The principal organ of the voice is the larynx; for, when it is injured, the air passes through the windpipe without yielding any sound.

Volsella. A probang, or instrument to remove bodies sticking in the throat.

VOLVULUS. (From volvo, to roll up ) The iliac passion, or inflammation in the bowels, called twisting of the guts.

VOLVULUS TERRESTRIS. Small bind-

weed. The convolvulus minof.

Named from its great resemblance to a plough-share. It is a slender thin bone separating the nostrils from each other, consisting of two plates much compressed together, very dense and strong, yet so thin as to be transparent; these two plates seem at every edge to separate from each other, and thus a groove is formed at every side .- 1. This groove, on the upper edge, or, as it may be called, its base, is wide, and receives into it the projecting points of the athmoid and sphenoid bones, and thus it stands very firmly and securely on the skull, and capable of resisting blows of considerable violence .-2. The groove, upon the lower part, is narrower, and receives the rising line in the middle of the palate plate, where the bones join to form the palate suture. At the fore part it is united by a ragged surface, and by something like a groove, to the middle cartilage of the nose, and as the vomer receives the other bones into its grooves, it is, as it were, locked in on all sides, receiving support and strength from each, but more particularly from the thick and strong membrane which covers the whole, and which is so continuous as to resemble a periosteum, or rather

thus the slender vomer possesses sufficient strength to advert from it all those evils which must inevitably have occurred, had it been less wisely or less strongly constructed.

VOMICA. (From vomo, to spit up; because it discharges a sanies.) An abscess of the lungs.

VOMICA LIQUORIS ÆTERNI.

VOMITING. Vomitio. A forcible ejection of food, or any other substance, from the stomach, through the esophagus and mouth. It is either idiopathic, when arising from a cause in the stomach itself: or symptomatic, when originating from diseases seated in any other part of the body. Its immediate cause is an antiperystaltic. spasmodic, convulsive constriction of the stomach and pressure of the diaphragm and abdominal muscles. It is an effort of nature to expel whatever molests or is tro blesome in the stomach.

Vaniting of blood. See Hamatemesis. VOMITUS CRUENTUS. See Hamatemesis.

Voracious appetite. See Bulimia Vox abscissa. Hourseness, a loss of voice. VULGAGO. The asarabacca was so called.

See Asarum.

VULNERARIA. (From vulnus, a wound.) Medicines which heal wounds. A herb named from its uses in healing wounds.

VULNERARIA AQUA. Arquebusade VULNUS SCLOPETICUM. gun-shot

wound.

VULVA. (Quasi valva, the aperture to the womb; or quasi volva, because the fætus is wrapped up in it.) The pudendum muliebre, or parts of generation proper to women; also a foramen in the brain.

VULVARIA. (From vulva, the womb; so named from its smell or use in disorders of the womb.) Stinking orach. See Atri-

plex olide.

Walnut. See Juglans. near Tewkesbury in Gloucestershire, con- fluid, made up of two substances, neither taining a small portion of iron dissolved in of which can be exhibited separately, exfixed air; of absorbent earth combined cept in the gaseous form; and when acriwith hepatic air; of vitriolated magnesia, form, they are known, the one as hydroand muriated mineral alkali; but the pro- gen gas, or inflammable air; the other as

portions of these constituent parts have not been accurately ascertained. Walton water is chiefly efficacious in obstructions and other affections of the glands.

WATER According to the Aqua. WALTON WATER. A mineral spring opinion of modern chemists is a compound WATER:

oxygen gas, or vital air. These gases, in which distinguishes it from pure water; the proportion of about three of hydrogen and the aqueous exhalation from living boto eleven of oxygen, when united chemi-cally, and reduced from the form of an air to that of a liquid, constitute the fluid,

It is transparent, without colour, smell, or taste; in every degree compressible; when pure, not liable to spontaneous change; hiquid in the common temperature of our atmosphere, assuming the solid form at 32° Fahrenheit, and the gaseous at 212°, but returning unaltered to its liquid state on resuming any degre of heat be- higher power than any other as a solvent of tween these points; capable of dissolving a greater number of natural bodies than any other flind whatever, and especially those known by the name of the saline; performing the most important functions in the vegetable and animal kingdoms, and entering largely into their composition as a constituent part. The simple waters are

the following: 1. Distilled water. This is the lightest of all others, containing neither solid nor gaseous substances in solution, is perfectly void of taste and smell, colourless and beautifully transparent, has a soft feel, and wets the fingers more readily than any other. It mixes uniformly with soap into a smooth opalme mixture, but may be added to a solution of soap in spirit of wine without injuring its transparency. clearness of distilled water is not impaired by the most delicate chemical re-agents, such as lime-water, a solution of barytes in any acid, nitrated silver, or acid of sugar. When evaporated in a silver vessel it leaves no residuum; if preserved from access of foreign matter floating in the air, it may be kept for ages unaltered in vessels upon which it has no action, as it does not possess within itself the power of decomposition. As it freezes exactly at 32° of Fahrenheit, and boils at 212° under the atmospherical pressure of 29.8° inches, these points are made use of as the standard ones for their mometrical division; and its specific weight being always the same under light pressure and temperature, it is employed for the comparative standard of specific gravity,

Pure distilled water can only be procured from water which contains no volatile matiers that will rise in distillation, and continue still in union with the vapour when condensed. Many substances are volatile during distillation, but most of the recommended as a fair subject of experigases, such as common air, carbon c acid, and the like, are incapable of uniting with water at a high temperature; other bodies, distilled water, is that which has underhowever, such as vegetable essential oil, gone a natural distillation from the earth, and, in general, much of that which gives and is condensed in the form of rain. This the peculiar odour to vegetable and animal is a water so nearly approaching to absoma ter, will remain in water after distilla- lute purity as probably to be equal to distion. So the steam of many animal and tilled water for every purpose except in

dies, which is a kind of distillation, has a

similar impregnation.

To obtain distilled water perfectly pure, much stress was laid by former chemists on repeating the process a great number of times; but it was found by Lavoisier, that rain water once distilled, rejecting the first and last products, was as pure a water as could be procured by any subsequent distillations.

Distilled water appears to possess a all animat and regetable matter, and these it holds in aution as little as possible altered from the state in which they existed in the body that yielded them. Hence the great practical utility of that kind of chemical analysis which presents the proximate constituent parts of these bodies, and which is effected particularly by the assistance of pure water. On the other hand, a saline, earthy, or otherwise impure water, will alter the texture of some of the paris, impair their solubility, produce material changes on the colouring matter, and become a less accurate analyser on account of the admixture of foreign contents.

Distilled water is seldom employed to any extent in the preparation of food, or in manufactures, on account of the trouble of procuring it in large quantities; but for preparing a great number of medicines, and in almost every one of the nicer chemical processes that are carried on in the liquid way, this water is an escential requi-site. The only cases in which it has been used largely as an article of drink, have been in those important trials made of the practicability of procuring it by condensing the steam of sea water by means of a simple apparatus adapted to a ship's boiler; and these have fully shown the ease with which a large quantity of fresh water of the purest kind, may be had at sea, at a mode. rate expense, whereby one of the most distressing of all wants may be relieved. There are one or two circumstances which seem to shew that water, when not already loaded with foreign matter, may become a solvent for concretions in urinary passages. At least, we know that very material advantage has been derived in these cases from very pure natural springs, and hence a course of distilled water has been ment.

2. Rain water, is the next in purity to vegetable decoctions has a certain flavour the nicer chemical experiments. The fo860 WATER.

reign contents of rain water appear to vary soilthrough which it flows. When the ingreaccording to the state of the air through dients are not such as to give any peculiar which it falls. The heterogeneous atmos- medical or sensible properties, and the phere of a smoky town will give some im- water is used for common purposes, it is pregnation to rain as it passes through, and distinguished as a hard or soft spring, this, though it may not be at once percep- sweet or brackish, clear or turbid, and the tible on chemical examination, will yet like. Ordinary springs insensibly pass into render it liable to spontaneous change; and hence, rain water, if long kept, especially in hot climates, acquires a strong smell, becomes full of animalcula, and in some degree putrid. According to Margraaff, the constant foreign contents of rain water appear to be some traces of the muriatic and nitric acids; but as this water is always very soft, it is admirably adapted for dissolving soap, or for the solution of alimentary or colouring matter, and it is accordingly used largely for these purposes. The specific gravity of rain water is so nearly the same as that of distilled water, that it requires the most delicate ins ruments to ascertain the difference. Rain, that falls in towns, acquires a small quantity of sulphat of lime and calcareous matter from the mortar and plaister of the houses.

3. Ice and snow water. This equals rain water in purity, and, when fresh melted, contains no air, which is expelled during freezing. In cold climates and in high latitudes, thawed snow forms the constant drink of the inhabitants during winter; and the vast masses of ice which float on the polar seas afford an abundant supply to the mariner. It is well known, that in a weak brine, exposed to a moderate freezing cold, it is only the watery part that congeals, leaving the unfrozen liquor proportionably stronger of the salt. The same happens with a dilute solution of vegetable acids, with fermented liquors, and the like; and advantage is taken of this property to reduce the saline part to a more concentrated form. Snow water has long lain under the imputation of occasioning those strumous swellings in the neck which deform the inhabitants of many of the Alpine valleys; but this opinion is not supported by any well-authenticated indisputable facts, and is rendered still more improbable, If not entirely overturned, by the frequency of the disease in Sumatra, where ice and snow are never seen, and its being quite unknown in Chili and in Thibet, though the rivers of these countries are chiefly supplied by the melting of the snow, with which the mountains are covered

Under this compre-4. Spring water. hensive class are included all waters that spring from some depth beneath the soil, and are used at the fountain head, or at least before they have run any considerable distance exposed to the air. It is obvious that spring water will be as various in its contents as the substances that compose the ture, it loses common air and carbonic

mineral springs, as their foreign contents become more notable and uncommon: though sometimes waters have acquired great medical reputation from mere pu-

By far the greater number of springs are cold; but as they take their origin at some depth from the surface, and below the influence of the external atmosphere, their temperature is, in general, pretty uniform during every vicissitude of season, and always several degrees higher than the freezing point. Others, again, arise constantly hot, or with a temperature always exceeding the summer heat; and the warmth possessed by the water is entirely independent of that of the atmosphere, and varies little winter or summer.

One of the principal inconveniences in almost every spring water, is its hardness, owing to the presence of earthy salts, which, in by far the greater number of cases, are only the insipid substances, chalk and selenite, which do not impair the taste of the water; whilst the air which it contains, and its grateful coolness, render it a most agreeable, and generally a perfectly innocent, drink; though sometimes, in weak stomachs, it is apt to occasion an uneasy sense of weight in that organ followed by a degree of dyspepsia. The quantity of earthy salts varies considerably; but, in general, it appears that the proportion of five grains of these in the pint will constitute a hard water, unfit for washing with soap, and for many other purposes of bousehold use or manufactures. The water of deep wells is always, ceteris paribus, much harder than that of springs which overflow their channel; for much agitation and exposure to air produce a gradual deposition of the calcareous earth; and hence spring water often incrusts to a considerable thickness the inside of any kind of tube through which it flows, as it arises from the earth. specific gravity of these waters is also, in general, greater than that of any other kind of water, that of the sea excepted. Springs that overflow their channel, and form to themselves a limited bed, pass insensibly into the state of stream, or river water, and become thereby altered in some of their chemical properties.

This is in general much 5. River water. softer and more free from earthy salts than ' the last, but contains less air of any kind; for, by the agitation of a long current, and in most cases a great increase of temperaacids, and, with this last, much of the lime ments to be a river of great purity. It which it held in solution. The specific might be expected that a river which has gravity thereby becomes less, the taste not passed by a large town, and received all so harsh, but less fresh and agreeable, and its impurities, and been used by numerous out of a hard spring is often made a stream dyers, tanners, hatters, and the like, that of sufficient purity for most of the pur- crowd to its banks for the convenience of poses where a soft water is required. plenty of water, should thereby acquire Some streams, however, that arise from a such a foulness as to be very perceptible clean siliceous rock, and flow in a sandy to chemical examination for a considerable or stony bed, are from the outset remark- distance below the town; but it appears, ably pure. Such are the mountain lakes from the most accurate examination, that and rivilets in the rocky districts of Wales, where the stream is at all considerable, the source of the beautiful waters of the these kinds of impurity have but little in-Dec, and numberless other rivers that fluence in permanently altering the quality flow through the hollow of every valley, of the water, especially as they are for Switzerland has long been celebrated for the most part only suspended and not truly the purity and excellence of its waters, dissolved; and, therefore, mere rest, and which pour in copious streams from the especially filtration, will restore the water mountains; and give rise to some of the to its original purity. Probably, therefinest rivers in Europe. An exceilent ob- fore, the most accurate chemist would find server and naturalist, the illustrious Haller, it difficult to distinguish water taken up at thus speaks of the Swiss waters, "vulgaribus aquis Helvetia super omnes fere Court, after each has been purified by Europæ regiones excellit. Nusquam h- simple filtration. quidas illas aquas et crystalli similimas se mili obtulisse memmi postquam ex Hel- present the greatest impurities to the vetia excessi. Ex scopulis enim nostræ senses, are those of stagnant pools, and per puros silices percolara nulla terra vi- low marshy countries. They are filled tiantur." Some of them never freeze in with the remains of animal and vegetable the severest winter, the cause of which is matter undergoing decomposition, and, probably, as Haller conjectures, that they during that process, becoming in part sospring at once out of a subterraneous reluble in water, thereby affording a rich servoir so deep as to be out of the reach of nutriment to the succession of living plants frost, and during their short course when and insects which is supplying the place of exposed to day they have not time to be those that perish. From the want of sufcooled down from 53°, their original tem- ficient agitation in these waters, vegetation perature, to below the freezing point

not take their rise from a rocky soil, and aquatic plants; and as these standing waare indeed at first considerably charged ters are in general shallow, they receive with foreign matter, during a long course, the full influence of the sun, which further even over a rich cultivated plain, become remarkably pure as to saline contents, but often fouted with mud, and vegetable or animal exuviæ, which are rather suspended than held in true solution. Such is that of ter. However, it should be remarked, the Thames, which taken up at London at low water, is a very soft and good water, and, after rest and filtration, it holds but a very small portion of any thing that could prove noxious or impede any manufacture. It is also excellently fitted for sea store; but it here undergoes a remarkable spontaneous change. No water carried to sea becomes purid sooner than that of the Thames. When a cask is opened after being kept a month or two, a quantity of inflammable air escapes, and the water is so black and affensive as scarcely to be borne. Upon racking it off, however, into large earthen vessels (oil jars are commonly used for the purpose), and exposing it to the air, it gradually deposits a quantity of black slimy mud, becomes clear as crystal, and remarkably sweet and palatable. The Seine has as high a reputation in France, and appears from accurate experi-

London, from that procured at Hampton

6. Stagnated waters The waters that goes on undisturbed, and the surface be-Some river waters, however, that do comes covered with converva and other promotes all the changes that are going on within them. The taste is generally vapid, and destitute of that freshness and agreeable coolness which distinguish spring wathat stagnant waters are generally soft, and many of the impurities are only suspended, and therefore separable by filtra-tion; and perhaps the unpalatahleness of this drink has caused it to be in worse credit than it deserves, on the score of salubrity. The decidedly noxious effects produced by the air of marshes and stagnant pools, have been often supposed to extend to the internal use of these waters; and often, especially in hot climates, a residence near these places has been as much condemned on one account as on the other, and, in like manner, an improvenient in health has been as much attributed to a change of water as of air.

thirds or three-fourths of the length of the corn. It is carried too far when the leafy germs have begun to sprout.

For this reason limits are set to the germination by drying the malt, which is effected by transferring it to the kiln, or by spreading it about in spacious airy lofts. Dried in the last way it is called air dried malt, in the first, kiln-malt. In drying this latter, care must be taken that it does not receive a burnt smell, or be in part converted into coal.

From this malt, beer is made by extraction with water and fermentation.

With this view a quantity of malt freed from its germs, and sufficient for one intended brewing, is coarsely bruised by grinding, and in the mash-tub first well mixed with some cold, then scalded with hot, water, drawn upon it from the boiler.

This second extract treated in like man-

WHEAT, TURKEY. The Turkey wheat occasioning a weeping from the urethrais a native of America, where it is much cultivated, as it is also in some parts of rhea, it will be very necessary to attend to Europe, especially in Italy and Germany. There are many varieties, which differ in is constant, but in a small quantity; there the colour of the grain, and are frequently is much ardor urine, itching of the pudenraised in our gardens by way of curiosity, whereby the plant is well known. It is tion to venery, and very frequently an en-the chief bread corn in some of the largement of the glands in the groin; southern parts of America, but since the whereas in the former the discharge is introduction of rice into Carolina, it is but irregular, comes away often in large lumps, little used in the northern colonies. It and in considerable quantities, and is makes a main part too of the food of the neither preceded by nor accompanied poor people in Italy and Germany. This with any inflammatory affection of the is the sort of wheat mentioned in the book of Ruth, where it is said that Boaz treated Ruth with parched cars of corn dipped in vinegar. This method of eating the roasted ears of Turkey wheat is still practised in the East; they gather in the ears when about half ripe, and having scorched them to their minds, eat them with as much satisfaction as we do the best flour bread.

In several parts of South America they parch the ripe corn, never making it into bread, but grinding it between two stones, mix it with water in a calabash, and so eat The Indians make a sort of drink from this grain, which they call bici. This liquor is very windy and intoxicating, and has nearly the taste of sour small beer: but they do not use it in common, being too lazy to make it often, and therefore it is chiefly kept for the celebration of feasts and weddings, at which times they mostly get intolcrably drunk with it. The manner of making this precious beverage, is to steep a parcel of corn in a vessel of water, till it grows sour, then the old women, being provided with calabashes for the purpose, chew some grains of the corn in discharge from the utcrus and vagina, of a their mouths, and spitting it into the cala- fluid which, in different women, varies bashes, empty them, spittle and all, into the much in colour, being either of a white, sour liquor, having previously drawn off green, yellow, or brown hue. In the bethe latter into another vessel.

The chewed grain soon raises a fermentation, and when this ceases, the liquor is complaint acquires the various discoloura-

WHITES. Fluor albus. Leucorrhaa. discharge is of so acrid a nature, as to produce effects on those who are connected with the woman, somewhat similar to venereal matter, giving rise to exceriations about the glans penis and preputium, and

To distinguish leucorrhæa from gonorthe symptoms. In the latter the running da, swelling of the labia, increased inclinapudenda.

Immoderate coition, injury done to the parts by difficult and tedious lalours, frequent miscarriages, immoderate flowings of the menses, profuse evacuations, poor diet, and abuse of tea, and other causes giving rise to general debility, or to a laxity of the parts more immediately concerned, are those which usually produce the whites, vulgarly so called, from the discharge being commonly of that colour.

Fluor albus, in some cases, indicates that there is a disposition to disease in the uterus, or parts connected with it, especially where the quantity of the discharge is very copious, and its quality highly acrimonious. By some the disease has been considered as never arising from debility of the system, but as being always a primary affection of the uterus. Delicate women, with lax fibres, who remove from a cold climate to a warm one, are, however, vcry apt to be attacked with it, without the parts having previously sustained any kind of injury.

The disease shews itself by an irregular ginning it is, however, most usually white and pellucid, and in the progress of the let off from the dregs, and set by till tions, and different degrees of acrimony, from whence proceeds a slight degree of thereby occasion much flatulency and eruc smarting in making water. Besides the tations of acid matter; heartburn and vio-discharge, the patient is frequently afflict- lent pains in the stomach from spasms are ed with severe and constant pains in the back and loins, loss of strength, failure of by passing into the intestines and mixing appetite, dejection of spirits, paleness of the countenance, chilliness, and languor. Where the disease has been of long contimance, and very severe, a slow fever, attended with difficult respiration, palpitations, faintings, and anasarcous swellings of the lower extremities, often ensues.

A perfect removal of the disorder will at all times be a difficult matter to procure; but it will be much more so in cases of long standing, and where the discharge is accompanied with a high degree of acri-In these cases, many disorders, such as prolapsus uteri, ulcerations of the organ, atrophy and dropsy, are apt to take place, which in the end prove fatal.

Where the disease terminates in death, the internal surface of the uterus appears, on dissection, to be pale, flabby, and relaxed; and where organic affections have arisen, much the same appearances are to be met with as have been noticed under the head of menorrhagia. See Leucorhæa.

Willow-leaved oak. See Quercus phellos. WINE. Vinum. The fermented juice of the ripe fruit of the Vitis vinifera of Linnæus :- foliis lobatis sinuatis nudis. The wines principally used in medicine are, the vinum album hispanicum, or mountain wine, vinum cauarium, canary or sack wine, the vinum rhenanum, or Rhenish wine, and the vinum rubrum, or Port wine. On a chemical investigation, all wines consist chiefly of water, alcohol, a peculiar acid, the carbonic acid, tartar, and an adstringent gummi-resinous matter in which the colour of the red wine resides, and which is expressed from the husks of the grape. They differ from each other in the proportion of these ingredients, and particularly in that of alcohol, which they contain. The qualities of wines depend not only upon the difference of the grapes, or sulphurated hydrogen, possess of preas containing more or less of saccharine cipitating lead in a black form, has been juice and the acid matter which accompa- long ago made public; snd this propernies it, but also upon circumstances at- ty has been employed to determine tending the process of fermentation. New the quality of wines by means of the liwines are liable to a strong degree of aces- quor probatorius Wirtembergensis, or Wircency when taken into the stomach, and temberg proving-liquor. But in trying

also often produced; and the acid matter. with the bile, is apt to occasion colics or excite diarrheas. Sweet wines are likewise more disposed to become acescent in the stomach than others: but as the quantity of alcohol which they contain is more considerable than appears sensibly to the taste, their acescency is thereby in a great measure counteracted. Red port, and most of the red wines, have an adstringent quality, by which they strengthen the stomach, and prove useful in restraining immoderate evacuations; on the contrary, those which are of an acid nature, as Rhenish, pass freely by the kidneys, and gently loosen the belly. But this, and perhaps all the thin or weak wines, though of an agreeable flavour, yet as containing little alcohol, are readily disposed to become acid in the stomach, and thereby to aggravate all arthritic and calculous complaints, as well as to produce the effects of new wine. The general effects of wine are, to stimulate the stomach, exhilarate the spirits, warm the habit, quicken the circulation, promote perspiration, and, in large quantities, to prove intoxicating, and powerfully sedative. In many disorders, wine is universally admitted to be of important service, and especially in fevers of the typhus kind, or of a putrid tendency; in which it is found to raise the pulse, support the strength, promote a diaphoresis, and to resist putrefaction; and in many cases it proves of more immediate advantage than the Peruvian bark. Delirium, which is the consequence of excessive irritability, and defective state of nervous energy, is often entirely removed by the free use of wine. It is also a well-founded observation, that those who indulge in the use of wine are less subject to fevers of the malignant and intermittent kind. In the putrid sore throat, in the small-pox, when attended with great debility and symptoms of putridity, in gangrenes, and in the plague, wine is to be considered as a principal remedy; and in almost all cases of languor, and of great prostration of strength, wine is experienced to be a more grateful and efficacious cordial than can be furnish. ed from the whole class of aromatics.

Method of discovering whether wine has been adulterated with any metals prejudicial to the health .- The property which the sulphuret of potash and hepatic air, wines supposed to have been adulterated, not to produce any vibration of the lathis proof does more harm than service, because it precipitates iron of the same colour as the pernicious lead. Many winemerchants of the greatest respectability rendered by these means suspected, have been ruined. There was wanting then a re-agent, which should discover in wine those metals only which are projudicial to the health of man.

The following liquor, precipitates lead and copper in a black form, and arsenic of an orange colour, &c. but does not precipitate iron, which is not noxious, and rather salutary to the constitution, and frequently gets into wines by accident.

Method of preparing the proving liquor — Mix equal parts of oyster-shells and crude sulphur in a fine powder, and put the mixture into a crucible; heat it in a wind furnace, and increase the fire suddenly, so as to bring the crucible to a white heat, for the space of fifteen minutes; pulve-rize the mass when it is cold, and preserve it in a bottle closely stopped. prepare the liquor, put 120 grains of this powder and 120 grains of cream of tartar (acidnlous tartrite of potash) into a strong bottle; fill the bottle with common water, which boil for an hour, and then let it cool; close the bottle immediately, and shake it for some time; after it has remained at rest to settle, decant the pure liquor, and pour it into small phials, capable of holding about an ounce each, first putting into each of them twenty drops of muriatic acid. They must be stopped them, which live in no other situation. very closely with a piece of wax, in which there is a small mixture of turpentine. One part of this liquor mixed with three parts of suspected wine, will discover, by a very sensible black precipitate, the least traces of lead, copper, &c. but will produce no effect upon iron, if it contains any of that metal. When the precipitate has fallen down, it may still be discovered whether the wine contains iron, by saturating the decanted liquor with a little salt of tartar, by which the liquor will immediately become black. Pure wines remain clear and bright after this liquor has been added to them.

WORMS. Vermes. There are several kinds of animals which infest the human body. Their usual division is into those which inhabit only the intestinal canal, as the ascarides, &c.: and those which are found in other parts, as hydatids. &c. Such is the nature and office of the human stomach and intestincs, that insects and worms, or their ovula, may not unfrequently be conveyed into that canal with those things, that are continually taken as food; but such insects, or worms, do not live long, and seldom, if ever, generate in a situation so different from their natural one. Besides these, there are worms that are never found in any other situation than the human stomach, or intestines, and which there generate and produce their species. Thus it appears that the human stomach and intestines are the seat for animalculæ, which are translated from their natural situation, and also for worms proper to

First Class.

This contains those which are generated and nourished in the human intestinal canal, and which there propagate their species.

Second Class.

Comprehends those insects or worms that accidentally enter the human primæ viæ ab extra, and which never propagate their species in that canal, but are soon eliminated from the body; such are several species of Scarabæi, the Lumbricus terestris, the Fasciola, the Gordins intestinalis, and others. The second class belongs to the province of natural history. The consideration of the first class belongs to the physician, which, from the variety it affords, may be divided into different

Order I. Round worms.

Genus I. Intestinal ascarides.

Worr. An infusion of malt. This has been found useful in the cure of the scurvy.

Dr. Macbride, in his very ingenious experimental essays, having laid down as a principle, "that the cure of the scurvy depends on the fermentative quality in the remedies made use of," was led to inquire after a substance capable of being

preserved during a long sea voyage, and yet containing materials by which a fermentation might occasionally be excited in the bowels. Such an one appeared to him to be found in malt, which is well known to be the grain of barley, brought suddenly to a germinating state by heat and mois-ture, and then dried, whereby its saccharine principle is developed, and ren. dered easy of extraction by watery liquors. The sweet infusion of this he proposed to give as a dietetic article to scorbutic persons, excepting that it would ferment in their bowels, and give out its fixed air, by the antiseptic powers of which the strong tendency to putrefaction in this disease might be corrected.

It was some time before a fair trial of this proposed remedy could be obtained; and different reports were made concerning it. By some cases, however, published in a postscript of the second edition of the Doctor's work, in 1767, it appears that scorbutic complaints of the most dangerous kinds have actually been cured at sea by the use of wort. Its general effects were to keep the patients open, and to prove highly nutritious and strengthening. It sometimes purged too much, but this effect was easily obviated by the tinctura thebaica. Other unquestionable cases of the London Medical Essays and Inquiries.

The use of wort has hence been adopted in other cases where a strong putrid disposition in the fluids appeared to prevail, as in cancerous and phagadenic ulcers; and instances are published in the fourth volume of the work above-mentioned of its remarkable good effects in these cases.

As the efficacy of the malt infusion depends upon its producing changes in the whole mass of fluids, it is obvious that it must be taken in large quantities for a considerable length of time, and rather as an article of diet than medicine From one to four pints daily have generally been directed. The proportion recommended in preparing it, is one measure of ground malt to three equal measures of boiling water. The mixture must be well stirred, and left to stand, covered three or four hours. It should be made fresh every day.

ZEA MAYS. the Indian wheat plant, a native of Ame- black, &c. and with various degrees of rica, and cultivated in Italy and several lustre and transparency. This zinc ore is parts of Europe, for its grain, which is contaminated with iron, lead, argillaceous ground for the same purposes as our wheat, and siliceous earths, &c. It occurs both to which it is very little inferior.

ZEDOARIA. 1 The name of a genus of plants in the Linnzan system. Class,

2 The pharmacopoial name of the blueish tint. It possesses some degree of Kampferia rotunda of Linnaus, foliis lanductility, and may be extended when ceolatis petiolatis. The roots of this plant carefully passed between metallic cylinders are brought to us in long pieces about in a flatting mill. Its specific gravity is the thickness of the little finger, two or 7.190. It melts at 700° Fahr. By a farthree inches in length, bent, rough, and ther increase of heat it is volatilized withangular, or in roundish pieces about an out change. When melted in contact with inch in diameter, of an ash colour on the the air, its surface becomes covered with outside, and white within. They have an agreeable camphoraceous smell, and a bitterish aromatic taste. Though formerly much esteemed against rheumatic affections, they are at present thought to possess very little medicinal powers, although they have a place in the confection aromatica of the London pharmacopæia.

ZEDOARIA LONCA. The long roots of

the Zedoaria rotunda of Linnæus.

ZEDOARIA ROTONDA. The systematic name of the zedoary plant. See Zedoaria. Zedoary. See Zedoavia.

ZERNA. An ulcerated impetigo. Lepra. ZIBETHUM. (From Zobeth, Arab.) Civetta. Civet. A soft unctuous odoriferous substance about the consistence of honey or butter, of a whiteish, yellowish, or brownish colour, sometimes blackish, contained in some excretory follicles near the thus of the Viberra zibetha of Linnæus. It has a grateful smell when diluted, and an unctuous subacrid taste, and possesses stimulating, nervine, and antispasmodic virtues.

ZINC. (Zincum, Germ.) A metal found in nature combined with oxigen, carbonic acid, and sulphuric acid; and mineralised by sulphur. Native oxid of zinc is commonly called calamine. It occurs in a loose, and in a compact form, amorphous, of a white, grey, yellow, or brown colour, without lustre or transparency. Combined with carbonic acid, it is called vitreous zinc ore, or native carbonate of zinc. It is found in solid masses, sometimes in

is generally greyish inclining to black. It is often transparent. Sulphate of zinc is found efflorescent in the form of stalacties ZARZA. An ancient and provincial name or in rhombs. Sulphuret of zinc, or blende, is the most abundant ore. It is found of The systematic name of various colours; brown, yellow, hyacinth, in amorphous masses and crystallized in a diversity of polygonal figures.

Properties of zinc .- Zinc on its fracture Monandria. Order, Monogynia. Zedoary. appears of a shining white colour, with a an imperfect oxid; when heated a little above ignition it burns with a bright yellowish white flame, slightly tinged with green, and a white oxid is formed in light flakes, which are carried off by the rapid current of air in the burning metal. It undergoes very little alteration from the air, its surface becomes slightly tarnished. It is not acted on by water at the usual temperature of our atmosphere, but at that of ignition, it decomposes this fluid rapidly. It is oxidated and dissolved by the greater number of the acids. It has a very strong attraction for oxigen, and therefore precipitates the greater number of the metals from their acid solutions. All the alkalis when digested or boiled with zinc blacken its surface and dissolve a minute portion of it. It decomposes muriate of animonia, sulphate of potash, and various other neutral salts. A mixture of nitrate of potash and zinc detonates with rapidity. Sulphur and zinc cannot be united by fusion. Gold, silver, platina, and nickel form brittle compounds with zinc. It easily unites with mercury and tin. It does not combine with lead or bismuth. The most frequent and at the same time most useful combination of zinc is that with copper. It unites with great difficulty to arsenic, iron, and cobalt. It inflames in oxigenated muriatic acid gas, and fulminates by pressure or a blow with oxigenated muriate of potash. It is a very strong conductor of galvanism. The use of zinc in the arts is very considerable. six-sided compressed prisms, both ends In medicine the sulphate of zinc, or white being covered with pentagons. Its colour vitriol, as it is called is given internally

in the dose of from Bj to 3ss, as a vomit. In small doses it cures dropsics, intermitting head-achs, and some nervous diseases, and is a powerful antispasmodic and tonic. A solution of white vitriol is also used to remove gleets, gonorrhoas, and for cleaning foul ulcers

Zinc, vitriolated. See Zinci sulphus.

Zingi. An ancient name of the stellated anniseed. Sec Anisum stellatum

ZINGIBER. (Ziy TiGopis, Indian.) Zingiber nigrum, Zingiber inger. Amonum zingiber giber album, commune. Ginger. of Linnxus. The white and black ginger are both the produce of the same plant, the difference depending upon the mode of preparing them. Ginger is generally considered as an aromatic, and less pungent and heating to the system than might be expected from its effects upon the organ of taste. It is used as an antispasmodic and carminative. The cases in which it is more immediately serviceable are flatulent colics, debility, and laxity of the stomach and intestines; and in torpid and phlegmatic constitutions to excite brisker vascular action. It is seldom given but in combination with other medicines. In the pharmacopæias it is directed in the form of a syrup and condiment, and in many compositions ordered as a subsidiary ingredient.

ZINGIHER ALBUM. The root of the amomum zingiber of Linnans is so termed when deprived of its radicles and sordes.

ZINGINER COMMUNE. See Zingiber. The root of the ZINGIHER NIGRUM. Amonum zingiber of Linnxus is so called

when suffered to dry with its radicles and the sordes which usually hang to it.

ZIRCON. An earth discovered in the year 1793, by Kl proth of Berlin, in the Zircon or Jargon, a gem first brought from the island of Ceylon, but also found in France, Spain, and other parts of Enrope. Its colour is either grey, greenish, yellowish, reddish-brown, or purple. It has little lustre, and is nearly opaque. is likewise found in another gem called the livacinth. This stone is of a yellowish red colour mixed with brown. It possesses

lustre and transparency.

Properties.—It has a white colour, is exceedingly heavy, and rough or harsh to the touch like silex. It has neither taste nor odour, and is insoluble in water, but forms with it a kind of jelly. melts with borax into a transparent colourless glass It suffers in a charcoal crucible a pasty fusion by intense heat, and centracts in its dimensions, acquiring a

grey colour and scintillating hardness. In this state it is very hard and insoluble in acids. Its specific gravity is 4.3. Neither air nor combustible bodies act upon it. It is soluble in water, but retains while drying in the air a large quantity of it, which gives it the semi transparency and appearance of a yellow jelly, or gum arabic; it exhibits the same vitreous fracture. It unites with all the acids and form salts, differing from those of the other bases by being decomposable by alumine, glucine, the alkalis, and by mere heat. with alumine and silex. It is insoluble. even by boiling in a solution of alkalis. neither can it be fused with them by means of heat; but it is soluble in alkaline carbonates.

By these properties this earth may be distinguished from every other. It is still

of no use in the arts.

Method of obtaining zircon.-Reduce the mineral to powder, mix it with three times its weight of potash, and fuse it in a crucible. Wash the obtained mass in distilled water, till the whole of the potash bc extracted; then dissolve the residuum as facas possible in diluted muriatic acid. Boil the solution to precipitate any silex it may contain, filter it, and gradually add solu-tion of potash. The zircon will now be-come precipitated. Wash it repeatedly in distilled water and dry it.

poral bone are so called.

ZYGOMATIC SUTURE. Sutura zygo. The union of the zygomatic promatica. cess of the temporal bone to the cheek

ZYGOMATICUS MAJOR. This muscle arises how the cheek bone near the

zygomatic suture, taking a direction down- angles of the mouth up as in laughter, and wards and inwards to the angle of the from, in this way, rendering the face dismouth; it is a long slender muscle, which torted, it has obtained the name of distor. ends by mixing its fibres with the orbicu- tor oris. The strong action of this muscle laris oris and the depressor of the lip.

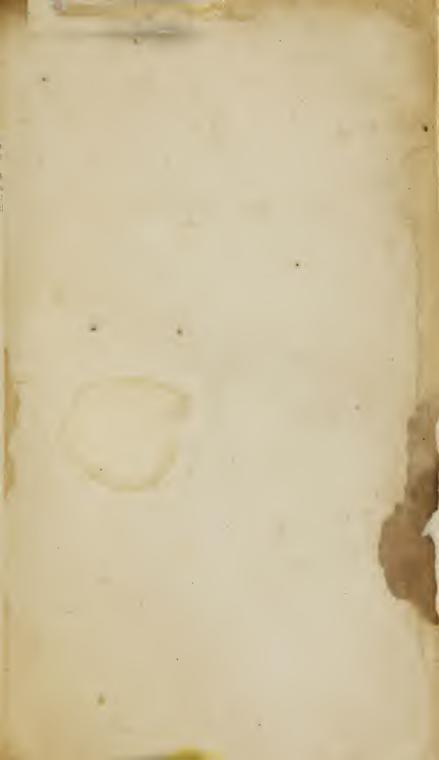

ZYGOMATICUS MINOR. This mus- or grinning. cle arises a little higher up than the zygomaticus major, upon the cheek bone, but which make together what we commonly nearer the nose; it is much more slender call posset-drink; a term often to be met than that muscle, and is often wanting. It with in Sydenham. is the zygomatic muscle that marks the face with that line which extends from the cheek these two letters, from Eurern, a name for bone to the corner of the mouth, which is it common amongst them; but the late particularly distinguishable in some per- writers use them only for the Zinziber, sons. The zygomatic muscles pull the ginger.

is more particularly seen in laughter, rage.

ZYTHOGALA. Ζυθογαλα. Beer and milk.

zz. The ancients signify Myrrh by
